# Assessing the Risk of Fiscal Distress for Public Pensions: 

# State Stress Test Analysis 

Greg Mennis, Susan Banta, and David Draine<br>The Pew Charitable Trusts<br>901 E Street NW<br>Washington, DC 20004

May 2018

This paper summarizes the results of a stress test simulation analysis on the largest government pension plans in 10 states under different economic scenarios and assumptions for policymaker behavior. The simulation model applies both deterministic and stochastic methods. The model also uses state-specific actuarial projections and revenue forecasts, as well as a common set of capital market assumptions. Results are calculated for a variety of actuarial and financial measures over 30 years, with particular attention to downside economic scenarios and different assumptions on how officials are likely to respond to resulting increases in pension costs based on past behavior. We find that poorly funded plans face the risk of unfunded liabilities and high costs, and in some cases, insolvency under scenarios where returns are lower than expected. Conversely, we find that states with well-funded pension systems have achieved this result through a combination of fiscal discipline and adherence to policies specifically designed to manage the impact of market volatility in low-return scenarios. Finally, stochastic analysis of the state plans reveals that contribution policy - in addition to the timing of investment returns is a significant factor influencing cost variability. We conclude that stress testing is not just an academic exercise, and recommend that it be a standard reporting practice for all public-sector retirement systems.

## I. Overview

State and local governments reported total unfunded pension liabilities of $\$ 1.6$ trillion at the end of fiscal year 2017 - a larger deficit in both absolute terms and as a percentage of U.S. gross domestic product (GDP) than at any time before the Great Recession. ${ }^{1}$ This funding gap is the result of lower-than-expected investment returns, shortfalls in making actuarially required contributions, and for some jurisdictions, unfunded benefit increases that were negotiated when systems were prospering. Pension deficits matter because the cost of paying for underfunded retirement obligations can constrain spending for other essential government programs and services, including education and transportation.

Indeed, state pension costs have nearly doubled as a percentage of available state revenue since fiscal year 2000, when the pension deficit reported by state and local governments in aggregate was approximately zero. ${ }^{2}$ During that same time frame, measures of investment risk for pension portfolios have more than tripled, as has the use of higher-cost alternative investments, including real estate, private equity, and hedge funds. From a financial accounting perspective, cash flow measures show increasing outflows to pay for benefits increasing significantly as the aging public workforce moves into retirement. This places further pressure on plans to maintain asset levels and leaves state funds less able to absorb unexpected costs and investment shortfalls. Looking forward, most funds are lowering their outlook for investment returns based on the expectation of reduced economic growth and continued low interest rates.

These factors indicate that public pension systems may be more vulnerable to an economic downturn than they have ever been. However, there has been limited analysis of the consequences of risky investment strategies combined with low funding levels on state budgets. Ultimately, benefits must be paid to retirees, meaning that state budgets could be strained with increased costs potentially extending across decades.

[^0]This paper examines the impact of lower investment returns and market volatility on state pension systems and budgets through the application of a rigorous stress test analysis. To assess the sustainability of pension plans, we included 10 states of varying fiscal health in our analysis: Colorado, Connecticut, Kentucky, New Jersey, North Carolina, Ohio, Pennsylvania, South Carolina, Virginia, and Wisconsin. ${ }^{3}$ The results of our analysis indicate that:

- States with both low funded levels and low contribution rates face the real prospect of pension system insolvency - the complete depletion of pension plan assets - under downside economic scenarios. The pension systems in New Jersey and Kentucky have the greatest exposure to system insolvency in our study.
- States with low funded levels that have already increased contributions are unlikely to face insolvency, but may struggle to improve funding levels and reduce costs if target investment returns are not met. The risk of permanent high costs is most acute in Pennsylvania and Connecticut.
- States with funding policies that are not designed to respond to market downturns are also at risk of fiscal distress. Colorado faces the greatest level of uncertainty due to an inflexible pension funding policy that does not automatically adjusted to offset lower-than-expected investment returns. Ohio also follows a fixed rate funding policy, but recent increases in contributions and cuts to benefits have mitigated the immediate risk of insolvency for the state's pension plans.
- In certain cases, states' actuarial funding policies are not fit for managing costs in an affordable and sustainable manner in the face of market volatility. This finding is informed by stochastic simulation analysis of two states that follow actuarial funding policies, but have very different results - Virginia and South Carolina.
- Current reporting on public pensions is not adequate to assess these risks.

Our findings also reveal positive results. North Carolina and Wisconsin both demonstrate how strong funding policies can help to ensure that public pension systems are sustainable and secure. In addition, there has been some initial progress on states' implementation of stress test analysis, both as part of regular reporting and to evaluate proposed reforms. For example, in 2017, acting on recommendations made by a legislative commission, Virginia adopted legislation requiring annual comprehensive stress testing of its state-sponsored retirement plans. This will ensure policymakers in Virginia are able to continually monitor the fiscal health of the retirement system and plan for potential unexpected costs if investments underperform over the long term.

Following in Virginia's steps, New Jersey enacted legislation requiring annual stress test reporting for its largest pension plans in January of this year. This is a significant step toward transparency for a state that has ranked among the worst funded pension systems in the nation, and will help New Jersey better plan for and manage the fiscal health of its pension funds going forward.

[^1]Connecticut has also adopted policies mandating annual stress testing of its public plans, while Pennsylvania is currently considering similar legislation. Overall, the number of states that have adopted mandatory stress test reporting has more than doubled to seven in a little over a year. ${ }^{4}$

We expect this trend to continue, particularly in light of a growing consensus among the professional standards boards in the field. In September of 2017, the Actuarial Standards Board adopted a new standard of practice for pension plan actuaries and administrators to disclose in their annual valuations the amount of risk - in terms of both cost and funding status - to which public pension plans are exposed. ${ }^{5}$ The newly adopted guidelines, effective in November of 2018, follow recommendations made in a Blue Ribbon Panel Report commissioned by the Society of Actuaries in 2014, and build upon changes in reporting requirements for state and local public pension funds mandated by the Governmental Accounting Standards Board (GASB) that same year. ${ }^{6}$

The methodology, analytic framework, and resulting simulation model applied in this paper build on these recommendations and reporting requirements and provide the most comprehensive approach to stress testing for public pensions that has been developed to date.

This is not an academic exercise. For example, reforms passed in 2017 in Pennsylvania were guided in part by stress test analysis provided by the state's independent fiscal office. And at the time of this writing, the Colorado legislature had just passed much-needed reforms informed by the results of a stress test analysis conducted by an independent consultant, as required by state law. That analysis matches closely with our examination of the Colorado, and bolsters the case for requiring publicly reported stress testing analysis in other jurisdictions, based on the findings of this report.

Our core recommendation is for the adoption of standard stress test reporting to better inform policymakers about the costs and risks associated with funding pension promises. At its most basic, these analyses can quantify the estimated impact of lower investment returns. However, we believe that comprehensive stress testing will not only help policymakers understand the volatility surrounding pension systems' investments, but also how decisions related to plan funding can affect the overall health of the pension system, the state budget, and ultimately, the ability to pay promised benefits.

[^2]
## II. Methodology

Stress testing is a simulation technique used on asset and liability portfolios to determine the impact of downside economic scenarios. It is a valuable method for determining how financial balance sheets will fare during a financial crisis or a period of low economic growth.

One of the most notable examples of stress testing comes from the Dodd-Frank Wall Street Reform and Consumer Protection Act. This legislation was passed in 2010 in response to the 2008 financial crisis, and requires the Federal Reserve to conduct annual evaluations of financial institutions' ability to maintain solvency under hypothetical adverse economic conditions. The scenarios presented in this paper apply similar principles to examine pension funds by assessing the impact of a recession, stock market losses, slower economic growth, and lower-thanexpected investment returns on pension fund balance sheets and government budgets.

In the context of public pensions, research related to stress testing has primarily been focused on investment performance, with specific attention to the probability and potential impact of lower-than-expected returns on actuarially required contribution. Financial economists have also cautioned against the attendant risks associated with current reporting practices, and have argued extensively for measuring pension liabilities and costs using more conservative assumptions. ${ }^{7}$ To that end, bond rating agencies now regularly analyze pension liabilities using lower assumed rates of return. ${ }^{8}$ And Pew's own research to date has reported on the diverse fiscal health of pension systems across the states using more precise measures to assess pension contribution adequacy. ${ }^{9}$

Other studies include simulations to evaluate the affordability of state pension plans based on the interaction of uncertain investment performance and pension funding contribution policies for typical state plans. ${ }^{10}$ More recently, analyses have emerged that include more extensive simulations to assess the volatility of investment returns based on current data for select state examples. ${ }^{11}$ Recognizing of the benefits of such analyses, the Society of Actuaries' Blue Ribbon Panel recommended in 2014 that stress testing be included in plans' annual financial reporting. ${ }^{12}$

[^3]However, risk management for public pension plans needs to extend well beyond return scenarios, to include assessments of the risks associated with benefit funding policies, policymaker behavior in making required contributions, and the broader economic environment. In addition, these assessments should address the potential costs associated with these risks, in terms of impact to government budgets. The stress test simulation model presented here was constructed to account for these risk factors and their potential impact on both pension system health and resources to pay for other core government services.

## Model Foundation

All stress test models are grounded on a foundation, or structure, which includes the inputs, the simulation itself, and the outputs. Our stress test simulation model follows this approach and comprises these three basic elements and their component parts:

1. Model Inputs. Inputs include actuarial projections, a complete suite of capital market and asset allocation assumptions, and state revenue forecasts.
2. Model Simulator. Simulations are conducted using both deterministic and stochastic methods.
3. Model Outputs. The model produces a set of custom outputs that includes actuarial, financial, and economic measures to assess plan fiscal health and compare projected pension costs to available resources.

Figure 1

## Inputs

The model inputs were selected to allow for both actuarial and financial analysis of state pension plans in the context of a state's ability to pay for the associated fluctuating costs. We compiled three major classes of inputs:

- Actuarial Projections: To provide a starting point for stress test simulations, actuarial projections establish a 30-year outlook for pension benefits, costs, and liabilities based on each plan's assumptions, including the assumed rate of return on investments.
- Capital Market and Asset Allocation Assumptions: Capital market assumptions, which incorporate forecasts of economic growth and inflation, as well as expected returns and volatility by asset class, were developed for a 30 -year, forward-looking time horizon. Asset allocations are based on the investment policy and target allocation for each state.
- State Revenue Forecast: A unique feature of the model is its ability to frame pension costs and debt in relation to budget capacity over the 30-year forecast period. This required the use of a consistent budget metric and application of a standard methodology to projected revenue growth for each of the 10 states.

## Actuarial Projections

Actuarial projections establish a 30-year outlook for pension benefits, costs, and liabilities. These projections, developed by The Terry Group, depend upon an accurate starting point for financial measures and demographics. The projections also utilize forward-looking assumptions around workforce and salary growth, rates of inflation, turnover, and retirement, as well as long-term mortality expectations.

Actuarial projections are included for a total of 18 pension plans across the 10 states. ${ }^{13}$ Because the organization of pension plans varies across states, we included state worker and teacher plans in every case, as these are typically the largest retirement plans in terms of total pension liability. For several states, these two plans also represent the sum of what is managed and reported at the state level. In others, we also included plans for local employees where the management and reporting for these plans prevented separation, and were deemed to have an immaterial impact on the results in any event.

The actuarial forecast component of the simulation model is also designed to facilitate projections under different economic scenarios and assumptions about the behavior of policymakers in making required contributions. The methodology for the actuarial projections is included in Appendix I. The appendix also includes discussion of how certain economic

[^4]assumptions, including inflation, are applied in a consistent manner across the different components of the simulation model. They are applied for purposes of stochastic simulation analysis and to supplement scenarios based on each state's return assumptions, which are also included in our study.

## Capital Market and Asset Allocation Assumptions

The capital market and asset allocation assumptions provide an independent estimate of the expected return for stocks, bonds, and other investments based on the investment policy and target allocation for each state. These assumptions were developed after reviewing the forecasts of major business, academic, and government institutions. ${ }^{14}$

Our capital market assumptions contain projections for a variety of financial, economic, and investment variables over time. Some of these variables pertain to the broad outlook for the U.S. economy, such as real gross domestic product (GDP) and inflation. The remaining indicators measure the performance and expected volatility for each asset class, including public equity (both U.S. and non-U.S.), bonds, real estate, and private equity. These factors are then applied to develop a 30 -year, forward-looking estimate of performance for each state's pension funds under both deterministic and stochastic simulation models.

In total, we developed return and risks assumptions for six asset classes: U.S. equity, non-U.S. equity, core bonds, private equity, real estate, and cash. Due to methodological constraints, we evenly distributed fund allocations to hedge funds across all asset classes and remapped commodities to real estate for pension plan portfolios containing these alternative investments. ${ }^{15}$

To better understand the expected returns and risk across the plans, we also applied our capital market model to a plan portfolio that is representative of the asset allocation for pension systems across the 10 states in our analysis. Typical pension funds in these states are invested 51 percent in stocks; 27 percent in fixed income and cash; and 22 percent in real estate and private equity. The resulting asset allocation has a projected median return of 6.4 percent over 20 years.

Although this is almost a full percentage point below the weighted average expected return of 7.2 percent among the plans modeled, most of the differences can be attributed to assumed rates of inflation. The stress test simulation model assumes annual inflation of 2 percent, based on projections of the Congressional Budget Office (CBO), while the average inflation assumption across the 10 states in our study, weighted by liability, is 2.5 percent. If plan return assumptions

[^5]were adjusted downward to match the CBO estimate, the difference in expected returns between the capital market and pension plan assumptions is minimal, as illustrated in Figure 2. ${ }^{16}$

Figure 2
Weighted State Average Assumed Rate of Return with and without Inflation
Most states assume inflation in the long term will be closer to 2.5 than 2 percent

Notes: State average assumed rate of return at 2 percent inflation is equal to the states' average assumed rate of return less the difference between plans' assumed inflation plus 2 percent; Assumed rate of return data is based on plans' most recently published valuations (20162017), and weighted by 2016 total pension liability. Sources: Comprehensive Annual Financial Reports (CAFRs), actuarial reports and valuations, or other public documents, or as provided by plan officials.

The distribution of returns under our capital market assumptions shows that 20-year returns have the potential to vary from 3.3 percent (a $10^{\text {th }}$ percentile scenario, meaning returns are expected to exceed that level 90 percent of the time) to 9.6 percent (a $90^{\text {th }}$ percentile scenario). In other words, in a scenario where returns over 20 years are expected to be 6.4 percent, the analysis indicates that there is an 80 percent chance they will fall between 3.3 and 9.6 percent (see Figure 6 or Appendix I for the full distribution).

The distribution of returns for the average portfolio was also used to inform an economic scenario used throughout our analysis that assumes returns of 5 percent over the long term. Specifically, this scenario was constructed to reflect expected returns for the average portfolio at approximately the $25^{\text {th }}$ percentile. At this level of probability, the capital market assumptions for the average portfolio produce an estimated return of 4.8 percent over 20 years and 5.0 percent over 30 years. Capital market assumptions and asset allocation are the primary inputs needed to simulate investment return volatility, and include broader economic assumptions that also apply to the forecast of state revenue.

[^6]
## State Revenue Forecast

The model utilizes states' own source revenue (OSR) from the U.S. Census Bureau Survey of State Government Finance as a consistent measure of resources against which to compare pension costs over time and under different scenarios. ${ }^{17}$ Because state revenues are not typically forecasted over the 30-year analysis period, we performed a simple evaluation of the historical relationship between gross state product (GSP) and own source revenue. We then applied the projected rate of growth in GSP as a proxy for state revenue growth to create a baseline projection starting with fiscal year 2017. ${ }^{18}$

Over the past 20 years, state revenue and GSP have been highly correlated, suggesting that GSP growth can reasonably be used as a proxy for state revenue growth. This approach has the added benefit of allowing for a clean integration with the forecast methods for our economic and capital market assumptions. Specifically, different projections for state GSP and OSR across scenarios are based on the underlying capital market assumptions for U.S. GDP and inflation, which are used to forecast investment returns.

There are some limitations to the use of own source revenue as a measure of states' resources. For example, other researchers have noted that OSR includes some revenue sources that states are unlikely to use to pay for pension liabilities, such as tuition fees at state universities. ${ }^{19}$ Further, states may be facing "revenue hills" - diminishing or even negative marginal returns from increased tax rates - which may constrain policymakers' ability to further raise taxes. ${ }^{20}$ Both issues result in estimates of revenue growth that may be slightly optimistic and therefore may inflate a state's ability to afford required increases in pension contributions

Although OSR growth provides a useful metric for evaluating the impact of pension costs on individual state budgets over time, it cannot be used for precise comparisons across states. This is because state-run pension plans vary in whether they include local government or school district employees and in the proportion of pension costs for those workers that is paid from the state budget. For example, some states fund teacher pensions entirely out of the state general fund, whereas in others much of costs for teacher retirement benefits are paid from school district or municipal budgets. ${ }^{21} \mathrm{Yet}$, on balance, the use of own source revenue provides a consistent point of reference against which to measure pension liabilities for an individual state

[^7]over time that grows at a rate that is highly consistent with state-level GSP growth. See Appendix I for further details.

Figure 3

## Ratio of State Own Source Revenue to Nominal Gross State Product (GSP)

Note: United States uses national gross domestic product; there is a discontinuity in gross state product between 1996 and the rest of the time series due to a change from SIC industry definitions to NAICS industry definitions. Years highlighted in gray above include any year in which at least one quarter was in recession, according to the U.S. Federal Reserve. Sources: U.S. Census Bureau; Bureau of Economic Analysis; Moody's Analytics.

## Simulator

The model is constructed to perform two basic types of stress testing: deterministic simulations and stochastic simulations.

- Deterministic simulations are used to test how portfolios perform under precise circumstances of our own design, typically by performing a single trial run for each year in the forecast. Each run strictly adheres to the same user-specified assumptions on investment returns and economic metrics.
- Stochastic simulations are used to model the probabilities of various financial outcomes given specified means and standard deviations of economic variables and market returns. Our stress test model generates 10,000 runs for each simulation.

The hundreds of thousands of trials provide a rich body of data with which to assess the fiscal health of public pension funds under a broad range of scenarios. Because the volume of data is exhaustive, we developed a standard set of fiscal metrics to succinctly and effectively summarize relevant impacts and outcomes.

## Outputs

We project pension assets and liabilities under different scenarios, along with estimates of the resources available to pay for benefits, to provide a full range of financial projections across all the scenarios applied in the model. The stress test simulation model summarizes results using a
comprehensive set of actuarial, economic, and financial accounting metrics. These include standard balance sheet, payment, contribution, and cash-flow metrics that assess fiscal health over time and provide forward-looking indicators of future fiscal challenges.

A brief discussion of each type of metric is provided below. Complete fiscal metrics results for each state can be found in Appendix II.

- Balance Sheet Metrics: These metrics include the level and change in pension assets on a market value basis, and the funded ratio of assets to actuarial liabilities at the plan's assumed rate of return. The ratio of pension debt to own source revenue, calculated using a lower discount rate for plan liabilities, is also included to reflect an approximate average long-term borrowing rate for state government bonds. These measures provide an indication of fiscal position for each forecast year and the foundation for assessment of solvency.
- Payment and Contribution Metrics: These metrics include annual measures of employer and employee contributions, normal cost, and payroll, as well as net amortization, to assess contribution sufficiency. ${ }^{22}$ Ratios of contributions to both own source revenue and payroll provide measures to assess pension costs as a share of state budget and workforce compensation, respectively. Payment and contribution measures are the building blocks for assessing the long-term cost to taxpayers of promised pension benefits.
- Cash Flow Metrics: These metrics are based on the difference between contributions and benefits (operating cash flow) and are applied mainly as an early indicator of long-term fiscal solvency for poorly funded plans. A primary example used throughout our analysis is the ratio of operating cash flow to assets. The calculation:
[(Total Contributions - Benefit Payments) / Plan Assets at the Beginning of the Year]
Most public pension funds exhibit negative operating cash flow, and this ratio provides a benchmark for the rate of return required to ensure that asset balances do not decline.

[^8]
## Research Questions

The stress test simulation model provides an analytic engine to rigorously study a range of uncertain outcomes related to the fiscal health of state pension systems and potential impacts to government budgets. To apply the model in a focused manner, given that the number of potential simulations is limitless, the output is based on a framework designed to address three key research questions (RQ):

RQ 1: How do we assess fiscal distress and which states are at risk?
RQ 2: How might lower investment returns affect pension costs and therefore state budgets in the long term?
RQ 3: What is the impact of economic volatility on pension fiscal health, given states' high exposure to stocks and other risky asset classes?

## RQ1: Assessing the Risk of Fiscal Distress

Researchers grapple with how to identify the characteristics of a plan at risk of fiscal distress. Here, we use the stress test simulation model to evaluate the likelihood that a state's pension plan will become insolvent and/or payments will become unaffordable, based on three criteria:

- Declining asset levels, due to negative operating cash flows, that exceed the offsetting impact of annual investment earnings assuming a 5 percent rate of return;
- A high probability that system assets will be depleted within 20 years, requiring a transition from pre-funding pension benefits to pay-as-you-go (pay-go); and
- The resulting transition to pay-go would require the state to dramatically increase contributions over a short time period.

A transition to pay-go is problematic because the state is forced to fund benefit payments entirely through current employee and employer contributions, which may ultimately require dramatic budget cuts, a substantial increase in new tax revenue, or some combination of both.

States with a negative cash flow ratio in excess of 5 percent will have a high likelihood of reductions in assets in any given year. As Figure 4 shows, declining assets can generate even less in investment returns in subsequent years, further accelerating this drawdown. This can lead to an increased risk of insolvency followed by a transition to pay-go funding.

Figure 4
Sample Plan Asset Losses in a Scenario with Accelerating Negative Operating Cash Flow
Funded status and operating cash flow can significantly affect a plan's long-term fiscal health

Source: The Pew Charitable Trusts.

## RQ2: Measuring Estimated Long-Term Costs

Even in the absence of fiscal distress, lower-than-projected returns will have long-term cost implications for state retirement systems, because pension plans rely on investment earnings to pay for a substantial portion of benefits over time. ${ }^{23}$ Lower returns translate into reduced asset levels and require more from the budget to pay for promised benefits. And, because governments may be constrained in their ability to channel more money into pension plans, it also means that states may not be able to achieve their goals of full funding going forward. In effect, lower or more volatile investment returns could mean that current high contribution rates become essentially fixed long-term costs.

We measure long-term costs by evaluating two ratios: total contributions to payroll and employer contributions as a percentage of own source revenue. Permanent high-cost plans are defined as those with total contributions projected to exceed 25 percent of payroll beyond the 30 -year forecast period. The 25 percent benchmark represents twice the estimated actuarial cost of benefits for a typical state defined benefit plan.

The ratio of contributions to own source revenue is applied to determine whether states have the capacity to further increase pension payments. Affordable payments are calculated based on

[^9]past behavior and defined as no more than a 50 percent increase in employer contributions as a percentage of own source revenue over the course of a decade.

## RQ 3: Evaluating the Impact of Financial Market Volatility

Deterministic simulations allow us to chart the effects on state pension systems of specific fixed rates of return and simplistic assumed models of policymaker behavior. However, stochastic simulations provide a more complete picture of the fiscal impact of market volatility and the effect of policy choices on managing that risk.

We use stochastic simulation methods to investigate the effects of volatility from two primary sources: the sequence of returns over the forecast period; and each state's pension contribution policy in response to the associated volatility. The model simulates 10,000 different trials per year, shedding light on minimum and maximum levels of fiscal health as well as cost over the measurement period.

## Analytic Framework

To answer these questions, we applied a two-part analytic framework to the stress test model foundation. First, we designed two economic scenarios that focus on the downside risk associated with lower-than-expected returns, including the effect of an economic recession. Second, we adopted two behavioral assumptions to model how policymakers respond to lower returns. These assumptions are based on a range of likely outcomes for pension funding and account for current plan funding policies, affordability, and past behavior.

Figure 5

## Pew's Analytic Framework

Two-part lens that helps generate a broad range of likely outcomes

Source: The Pew Charitable Trusts.

## Economic Scenarios

Shortfalls in investment performance, relative to expected returns, explain approximately 50 percent of the increase in unfunded pension liabilities reported by states in 2016. ${ }^{24}$ As a result, examination of downside investment risk is at the heart of stress test analysis of public pensions. The analytic framework applied in our model includes two downside investment return scenarios: a fixed 5 percent return scenario and a scenario that accounts for an asset shock - a steep decline in asset values, as typically occurs during the onset of a recession - followed by low returns. ${ }^{25}$ By conducting a deterministic simulation using these two scenarios, we were able to examine plan solvency (RQ1) and the potential cost of downside risk (RQ2).

## Scenario 1: Fixed 5 Percent Returns

In the first economic scenario, which we call the fixed 5 percent return scenario, a single low rate of return is applied to the model for each year in the forecast period. The purpose of this scenario is to assess how plans perform when investment returns are lower than expected over the long term. Although most financial experts do not project returns this low in the coming years, they do expect investments to perform below historical averages. ${ }^{26}$

We selected 5 percent for this scenario for two reasons. First, given public plans trend toward 7 percent assumed rates of return, a low return scenario of 2 percentage points below that falls between the low return investment scenario required by the GASB ( 1 percentage point below the plan assumption) and the recommendation of the Society of Actuaries Blue Ribbon Panel ( 3 percentage points below the plan assumption). ${ }^{27}$ Second, 5 percent is in line with the stochastic analysis of our capital market assumptions, which generate a $25^{\text {th }}$ percentile return of about 5 percent over 30 years. In other words, there is a 50 percent chance, based on these assumptions, that long-term returns will be between 4.8 and 8.1 percent - a range that includes the 5 percent low return scenario. ${ }^{28}$

[^10]Figure 6

## Distribution of Stochastic 20-Year Returns for a Typical Portfolio

Typical portfolio has expected return of 6.4 percent at the median

Percentiles
Notes: Labels are for returns at the 10th, 25th, 50th, 75 th, and 90th percentile. Typical portfolio has 51 percent stocks, 27 percent fixed income/cash, and 22 percent in alternatives (i.e. private equity and real estate). Sources: The Terry Group and The Pew Charitable Trusts.

## Scenario 2: Asset Shock

In our second economic scenario, which we refer to as the asset shock scenario, we incorporated an initial decline in the stock market and loss in pension asset values followed by low returns over the long term. The scenario is based on the Federal Reserve's "2017 Supervisory Scenarios for Annual Stress Tests Required under the Dodd-Frank Act Stress Testing Rules." ${ }^{29}$

The asset shock scenario assumes an approximate 20 percent loss in asset value in year one, followed by three years of recovery. The trajectory here is similar to that seen after the start of the Great Recession. For 2018 to 2021, we based our assumptions of real GDP growth, inflation, interest rates, and public equity performance on those specified by the Federal Reserve under Dodd-Frank. ${ }^{30}$ In addition, we modified the scenario to also include a persistent low rate of return of 5 percent for equities from year five to year 30 .

[^11]Figure 7

## Investment Returns in Hypothetical Asset Shock Versus Great Recession

Asset losses larger and market rebound gains smaller in asset shock scenario

## Behavioral Assumptions

Although modeling market downturns is at the heart of stress testing, policymakers' responses to investment losses are a source of equal risk to plans' fiscal health, and therefore should be accounted for as part of a comprehensive stress test analysis. Our model examines two behavioral assumptions: first, that states increase funding to offset losses based on written state policy; and second, that policymakers limit increases to mitigate spending cuts in other areas of the budget.

Most states have formal fixed or actuarial funding policies written in statute. When investment returns are lower than expected, most policies call for increased payments to offset the impact and ensure the state remains on target for 100 percent actuarial funding by a preset date. Historical data indicate that state and local governments generally do respond to rising unfunded liabilities by increasing pension contributions, to some degree, as a share of government budgets. At the same time, policymakers also tend to modify funding policies - usually by stretching out the full funding date - to limit the size of the increase in pension costs in any given year.

For example, between 2003 and 2013, state pension contributions as a percentage of own source revenue increased from 4 to over 6 percent, while the amount needed to meet actuarial funding requirements went from 4 to 8 percent. Despite the increase in contributions, the average payment schedule for paying down unfunded liabilities (amortization period) during this time was essentially unchanged, meaning states continued to have long amortization periods that allowed little progress in paying down their pension debts (see Figures 8 and 9).

Figure 8
50 State Analysis: Actual Contribution as a Share of Own Source Revenue, 2001 to 2016
Overall, contributions nearly doubled over this time

Sources: Public Plan Comprehensive Annual Financial Reports, 2003-2013, and the U.S. Census Bureau's Annual Survey of State Government Finances.

Figure 9
50 State Analysis: Average Amortization Period for Open and Closed State Plans that are Level Percent of Pay, 2001-2016
Amortization periods increased in the early 2000s and after the Great Recession

Note: Includes 87 state and teacher plans. Observations of plans with an aggregate actuarial cost method are excluded. Source: Boston College Public Plans Database.

The analytic framework applied to our model accounts for the growth in pension contributions and the stagnation of amortization periods by including two behavioral assumptions: a sustainable budget assumption and a state policy assumption.

## Assumption 1: Sustainable Budget

In the sustainable budget assumption, contributions are set at a fixed percentage of state revenue. The assumption tracks closely with what states currently expect to contribute to their pension systems, if all plan assumptions are met. The sustainable budget assumption implicitly sets a limit on what is affordable to avoid additional strain on the state's budget at a time when other state obligations may also require increases in funding.

## Assumption 2: State Policy

In contrast to the sustainable budget assumption, the state policy assumption assumes strict adherence to current actuarial funding requirements based on states' written contribution policies. The best-case result from the perspective of pension funding is a rapid increase in contributions, to fully offset lower investment returns. Because this increase occurs at the worst possible time for the rest of the state budget, we also calculate a benchmark for fiscal capacity, called tolerance for payment.

The tolerance for payment metric, which is based on past behavior, assumes that policymakers are willing to increase payments over a 10-year period by the same amount as payments have increased, over the previous 10 years, measured as a percentage of state revenue. Based on fiveyear rolling averages, the 10 states in our study have increased contributions based on this tolerance for payment measure by approximately 3 percentage points. A further increase of 3 percentage points would translate, on average, to approximately a 50 percent increase in payments over 10 years relative to available budget resources. The tolerance for payment metric is used as a benchmark to assess whether increases in required contributions from the simulation model output are likely to be affordable.

Figure 10
50-State Analysis: Tolerance for Payment, Five-Year Rolling Average of Employer Contributions as a Share of Own Source Revenue for 2016 Compared with 2006
Historical increases about 50 percent at the median

Note: 10 states in Pew's analysis are highlighted in gold above. Sources: Public plan comprehensive annual financial reports, 2000-2016, and the U.S. Census Bureau's Annual Survey of State Government Finances.

The two assumptions for contribution behavior - sustainable budget and state policy - provide a range of likely funding levels for different investment return scenarios. In our simulations, the sustainable budget assumption, in which scarce state resources are appropriated evenly across pensions and other budgetary priorities, becomes the lower bound for projecting contributions. The state policy assumption, in which pension contributions are determined per written policy, serves as the upper bound. Based on past performance, we project future behavior to fall somewhere in between these two assumptions. In circumstances where the state policy calls for increases that may be especially difficult to reach, we also analyze results based on the tolerance for payment limit.

## Data Sources

We used a variety of sources to construct baseline and scenario assumptions, including the Federal Reserve, the Bureau of Labor Statistics, and the Congressional Budget Office. ${ }^{31}$ The investment and actuarial data sources used for this analysis are primarily from Pew's stress test simulation model, which employs data collected from comprehensive annual financial reports, as well as actuarial reports and valuations. State revenue assumptions were developed using historical data from the U.S. Census Bureau's Annual Survey of State Government Finances. For

[^12]gross state product, historical data came from the Bureau of Economic Analysis and projections from Moody's Analytics starting in 2017. We also constructed deterministic scenarios using sources from the Federal Reserve, the Bureau of Labor Statistics, and the Congressional Budget Office. Data sources for the development of capital market assumptions include the Congressional Budget Office, the Federal Reserve, the NCREIF National Property Index, FACTSET, and the Cambridge Associates LLC U.S. Private Equity Index.

Contribution policy assumptions for each pension plan come from comprehensive annual financial reports, actuarial reports and valuations, and other public documents or information as provided by plan officials. Contribution policy behavior was also informed by data from Boston College's Public Plans Database. A detailed table of each plan's assumptions - including contribution policies - can be found in Appendix II.

## III. Results and Findings

The states we chose to evaluate - Colorado, Connecticut, Kentucky, New Jersey, North Carolina, Ohio, Pennsylvania, South Carolina, Virginia, and Wisconsin - represent a range of fiscal positions and policies. The differences among these states allow us to use the stress test simulation model to demonstrate how market volatility and economic uncertainty can affect pension costs depending on a state's current financial status and contribution rules.

Kentucky and New Jersey: The state-sponsored pension plans in Kentucky and New Jersey were selected to assess their potential for insolvency as outlined in Research Question 1 (RQ1). Both states rank worst in the nation across a range of fiscal metrics, each reporting only 31 percent of assets on hand to pay for promised benefits, the lowest funded ratios in the country. We conclude that both states face the risk of pension system insolvency under the fixed 5 percent return scenario, if public officials fail to raise state contributions as required under recently adopted reforms.

Pennsylvania and Connecticut: Connecticut and Pennsylvania also rank near the bottom on pension funding alongside Kentucky and New Jersey but have stabilized system financing by following through on policies that increase employer contributions and reduce pension liabilities. As such, Connecticut and Pennsylvania were selected to assess Research Question 2 (RQ2), by determining whether these policies will be sufficient to achieve full funding, and reduce budget costs, even in the case of lower investment returns. We conclude that, for both states, increases in required contributions under these conditions may be unaffordable, and that public officials may potentially modify state policy and stretch out high pension costs beyond the 30-year forecast period.

Colorado and Ohio: Although not as fiscally challenged as Kentucky or New Jersey, neither Colorado nor Ohio has policies in place that respond to economic downturns, as both states set contributions as a statutorily fixed percentage of pay. We conclude that without policy intervention, Colorado faces the risk of pension system insolvency in a low-return environment. The outlook in Ohio is less dire, in large part because the state has implemented significant benefit reductions in years past, but policymakers may be forced to revisit a narrowing set of policy options when there is another economic recession.

Virginia and South Carolina: South Carolina's fiscal metrics place the state in the bottom 10 in the nation - about the same as Colorado - while Virginia tracks closely to the national average. We selected South Carolina and Virginia because they have more traditional actuarial funding policies, which allows us to assess Research Question 3 (RQ3), regarding the impact of financial market volatility on pension costs and the role state funding policies play in addressing this risk. We conclude that for poorly funded states like South Carolina, policymakers need to evaluate whether pension system finances can absorb an extreme one-time shock in the stock market, based on the Federal Reserve scenario. Separately, results in Virginia using stochastic analysis reveal substantial volatility in pension costs, even at expected rates of return, and point to the need to better calibrate actuarial funding policies to avoid such a level of budget uncertainty.

North Carolina and Wisconsin: Finally, we chose North Carolina and Wisconsin to evaluate how two of the best-funded systems in the country are expected to weather the next economic downturn, with particular focus on their fundamentally different policies. North Carolina has a robust contribution policy, and the state can be counted on to pay every bill in full, each year, regardless of market fluctuations. Wisconsin is equally diligent when it comes to maintaining contribution levels, but the state's defined benefit plan is also designed to share the risk of unexpected costs between employees and employers.

Our key findings for the 10 states are discussed below, and detailed tables of fiscal metrics for each state are provided in Appendix II. The results reflect the impact of pension reforms and other policy changes enacted through March 2018. For example, in Connecticut and Pennsylvania, the adoption of risk-managed hybrid plans for new workers is factored into our analysis, which projects substantial cost containment under low return scenarios. We also include reference to the most recent reforms passed in Kentucky and Colorado, in April and May respectively. However, the financial impact of these two reforms were not included in our analysis.

Based on the results of our stress test simulations, New Jersey and Kentucky are most at risk of pension system insolvency. The public pension systems in both states have seen reported funded levels decline from over 100 percent in fiscal year 2000 to 31 percent as of 2016. New Jersey and Kentucky are now the two lowest-funded state pension systems in the country, and have the lowest operating cash flow to assets ratios (see Figure 11). In both cases, our analysis demonstrates the real risk that plan assets could be fully depleted in a scenario where investment returns are lower than expected, unless the states firmly adhere to recent reforms to strengthen pension finances.

Figure 11
50-State Analysis - Funded Ratio (FY 2016) and Operating Cash Flow to Assets Ratio (Average FY 2014-2016)
New Jersey and Kentucky rank worst among the 50 states

Notes: The eight other states in Pew's analysis are highlighted in gold above. Sources: Comprehensive annual financial reports, actuarial reports and valuations, or other public documents, or as provided by plan officials.

## New Jersey

The results for New Jersey demonstrate the potential effect of pension system insolvency on the state budget. A simulation using the fixed 5 percent return scenario and assuming sustainable budget contributions - i.e., without adjusting for recently adopted plans to triple pension contributions over the next five years - shows the state's pension fund assets would decline at an accelerated rate until reaching zero by the end of 2029 (see Figure 12). ${ }^{32}$ Once insolvent, future benefit payments for the plans would be directly paid out of employee contributions, the lottery revenues newly dedicated towards the pension funds, and the state's budget. This would increase the state's annual cost from about $\$ 5$ billion in 2029 to almost $\$ 7$ billion in 2030, the first year of projected insolvency (or $\$ 6$ billion to $\$ 8.5$ billion including employee contributions, as illustrated in Figure 13). Furthermore, from 2018 to 2028 alone, reported pension debt in this scenario would balloon from $\$ 56$ billion to $\$ 101$ billion. ${ }^{33}$

Figure 12

## New Jersey's Projected Assets and Operating Cash Flow

Under fixed 5 percent returns scenario and applying the sustainable budget contribution assumption

[^13]Figure 13

## New Jersey's Projected Contributions and Benefit Payments

Under fixed 5 percent returns scenario and applying the sustainable budget assumption

Note: Assumes actual investment returns of 5 percent and employer contributions are fixed as a percentage of own source revenue (sustainable budget). Sources: The Pew Charitable Trust and The Terry Group, based on publicly available comprehensive annual financial reports, actuarial reports and valuations, or other public documents, or as provided by plan officials.

To avoid fiscal distress and protect the state employee and teacher pension plans from insolvency, New Jersey will need to rigidly adhere to the newly adopted funding policies (see Figure 14). We anticipate this to be a challenge. The lottery revenue accounts for only about one quarter of total required contributions over the next five years, and Pennsylvania is the only state to date that has successfully raised contributions this rapidly over such a limited time frame. In addition, New Jersey's track record for making annual required contributions is weak - our research places the state last among the 50 states in making actuarial required contributions since fiscal year 2000.

Figure 14

## New Jersey's Annual Required Contributions (ARC) Compared with Actual Contributions

Ramp-up calls for going from paying 30 percent of ARC in 2016 to full payment in 2023 - a $\$ 5$ billion increase annually.

Note: Data for the New Jersey PERS and TPAF plans, state portion only; does not include contributions by local employers. Simulated model figures represent the ramp up contribution policy. Sources: The Pew Charitable Trust and The Terry Group (2017-2027), based on publicly available comprehensive annual financial reports, actuarial reports and valuations, or other public documents (2000-2016).

## Kentucky

Kentucky's fiscal condition is less dire than New Jersey's, assuming policymakers abide by recent changes to funding policies; however, our results for Kentucky's state and teacher plans vary, with the state's largest plan facing a significant risk of fiscal distress during the forecast period.

Specifically, projections for the Kentucky Employee Retirement System (KERS) reveal that a \$500 million increase in annual funding committed by the state in 2017 has altered the fiscal trajectory for the plan and placed it on more solid financial footing. Separately, analysis of the Kentucky Teachers Retirement System (KTRS) — completed before April 2018 pension reforms were signed into law, projects that the teachers' plan would reach insolvency by 2036 under a fixed 5 percent return scenario and the sustainable budget assumption (Figure 15). ${ }^{34}$ Given the relative size of KTRS, such an outcome would result in significant fiscal distress for the statewide system overall under these conditions. ${ }^{35}$

However, the April 2018 reforms may provide some fiscal relief for Kentucky's pension systems. At the time of this writing, the state had just adopted additional reforms - most significantly, an actuarial funding policy for KTRS. Because these changes occurred after our analysis, and are currently being challenged in the courts, they were not included in our simulations. ${ }^{36}$ However, if the state adheres to this stronger funding policy, its risk of insolvency will largely be constrained, though like Pennsylvania and Connecticut, Kentucky may face high and potentially volatile costs indefinitely.

[^14]Figure 15
Kentucky's Projected Assets and Operating Cash Flow - May 2018 Analysis
Under the fixed 5 percent returns scenario and the sustainable budget assumption

## Pennsylvania and Connecticut: Risk of Permanent High Costs

Along with New Jersey and Kentucky, the pension plans in Pennsylvania and Connecticut have funded ratios that rank among the lowest in the nation. But, in contrast, Pennsylvania and Connecticut are in nominally better shape, thanks to recent reforms in which both states increased contribution rates to more than 30 percent of payroll (see Figure 17). That said, our stress test simulations found that both states are likely to see these current high levels of cost persist for as long as 50 years if returns fall short of expectations.

Figure 17
Employer Contribution Rates for Pennsylvania and Connecticut Over Time
Under current plan assumptions for both states

Sources: The Pew Charitable Trust and The Terry Group, based on publicly available comprehensive annual financial reports, actuarial reports and valuations, other public documents, or as provided by plan officials.

We reached this conclusion by conducting a deterministic simulation and using the same fixed 5 percent return scenario used to evaluate New Jersey and Kentucky. If Pennsylvania and Connecticut follow their state policy assumptions, both would face substantial increases in cost that could further limit budget capacity for other state spending. As a result, there is a significant risk that state officials will modify current policy to mitigate further spikes in pension costs by extending amortization schedules. Should that occur, costs and unfunded liabilities could remain at, or around, current levels until well beyond the 30-year forecast period.

## Pennsylvania

From 2000 to 2016, Pennsylvania's pension systems went from a $\$ 16$ billion surplus to a $\$ 69$ billion deficit. This $\$ 85$ billion deterioration in fiscal position was caused by persistent underfunding, lower-than-expected investment returns, and one of the largest unfunded benefit
increase that any state has implemented. ${ }^{37}$ In response, the state has enacted two rounds of reform since the financial crisis, dramatically ramping up employer contributions to stabilize pension financing and shifting new workers to a risk-managed hybrid plan to lower taxpayer risk. ${ }^{38}$

We estimate that current levels of high cost are likely to persist for decades in a scenario with significantly lower returns, because further increases in required state contributions may be unaffordable. Specifically, if returns are lower under the fixed 5 percent return scenario, we estimate that contributions would increase from 32 percent to 41 percent within the forecast period. This increase is equivalent to approximately 8 percent of state revenue (see Figure 18).

## Figure 18

Pennsylvania's Projected Employer Contributions and Pension Debt
Under the fixed 5 percent returns scenario and the state policy assumption

Note: Assumes actual investment returns of 5 percent and applying the assumption that the state adheres to current funding policies or statute as written (state policy). Sources: The Pew Charitable Trust and The Terry Group, based on publicly available comprehensive annual financial reports, actuarial reports and valuations, other public documents, or as provided by plan officials.

The additional increases in funding required by Pennsylvania's current policy under a 5 percent return scenario may prove difficult. The rapid escalation in funding over the past five years is already the largest any state has implemented over that time frame, and, in the absence of increased resources, has displaced approximately $\$ 10$ billion in other government spending. ${ }^{39}$ As such, the legislature's willingness to further increase spending on pensions is likely to be limited if it were to crowd out spending for other core government services.

[^15]Because of this, we project that higher unfunded liabilities and payments well above the 25 percent of payroll benchmark identified in the Methodology section, will continue beyond the current forecast period. This result provides a direct and sobering response to research question number two on the impact of investment shortfalls on pension costs. For states like Pennsylvania with low funded levels that may already be at budget capacity for funding pensions, it may be difficult for their retirement systems to achieve fully funded status and the attendant reduction in costs within a 30-year time horizon if returns fall short of current targets. As a result, the state's continued attention to managing unfunded liabilities, including a current study to lower investment fees and to adopt regular stress test reporting, is essential.

## Connecticut

The root cause of Connecticut's 41 percent funded ratio, among the lowest across the 50 states, was a considerable delay in adopting sufficient actuarial pre-funding policies for its state employee and teacher pension plans. ${ }^{40}$ Like Pennsylvania, Connecticut improved funding practices in recent years - making 100 percent of ARC payments for over a decade - and also adopted a hybrid plan for state workers in 2017. ${ }^{41}$

The stress test results for Connecticut's retirement systems highlight the positive effect of higher contribution rates in staving off the risk of insolvency. Under the fixed 5 percent return scenario with sustainable budget contributions, for example, asset levels still increase over time. However, like Pennsylvania, projected outcomes under the state policy assumptions also highlight the risk of high long-term costs.

If Connecticut were to follow its current state funding policy under the fixed 5 percent return scenario, the required contribution rate is projected to reach over 80 percent of payroll during the 20 -year forecast period (Figure 19). This spike would push pension contributions from 14 percent to over 20 percent of annual revenue, consuming more than $\$ 1$ billion of addition available revenue on an annual basis. Adherence to such a substantial schedule of payments is highly unlikely. Indeed, our analysis found required contributions closely mirror or exceed the state's tolerance for payment - as defined in the Methodology section of this analysis throughout much of the forecast period under this scenario. ${ }^{42}$

[^16]Figure 19

## Connecticut's Projected Employer Contributions and Pension Debt

Under the fixed 5 percent returns scenario and applying the state policy contribution assumption

Note: Assumes actual investment returns of 5 percent and that the state adheres to the current funding policies or statutes as written (state policy). The tolerance for payment assumes that over 10 years payments as a share of payroll cannot grow by more than 50 percent of OSR. Sources: The Pew Charitable Trust and The Terry Group, based on publicly available comprehensive annual financial reports, actuarial reports and valuations, or other public documents, or as provided by plan officials.

The clear finding for Connecticut is that market downturns could increase that cost beyond the state's capacity to pay under the current funding policy. As a result, current high costs are likely to persist for decades under scenarios where investments underperform.

## Colorado and Ohio: Greatest Uncertainty

What sets Colorado and Ohio apart from the other eight states analyzed here is their fixed-rate funding policies, which are based on a set percentage of covered payroll and do not provide a mechanism for increasing state contributions to offset the effect of market downturns. This contrasts with other states that employ actuarial funding methods that respond to increases in unfunded liabilities by prescribing higher contributions.

The consequence of this inflexible approach to funding pension obligations is reflected in historical results and reinforced through the stress test results for both states. In Colorado, persistent underfunding explains most of the rapid decline in fiscal position between 2000, when the state reported a funded ratio of more than 100 percent, to the 2016 reported figure of only 52 percent. Pension finances in Ohio are more stable, as their primary response to growing unfunded liabilities was the enactment, following the Great Recession, of one of the largest reductions in pension benefits any state has implemented.

Looking forward, both states' fixed-rate funding policies cause heightened uncertainty around how policymakers will address unfunded pension liabilities if future investment returns are lower than expected. Of the 10 states studied here, Colorado and Ohio face the greatest fiscal uncertainty over the next 20 or 30 years, with Colorado facing a significant risk of fiscal distress.

To reach this conclusion, we conducted a deterministic analysis using the fixed 5 percent return scenario and kept contributions at budget sustainable levels. The output from the stress test model forecasts a 51 percent reduction in pension fund assets over 20 years for Colorado, which is a clear early indicator of fiscal distress (see Figure 20). Although recent policy changes in Ohio prevent the state's pensions from similar projected insolvency, the funded ratio for Ohio would drop to just 54 percent and operating cash flow would approach -6 percent over the same period. These findings are based on the same sustainable budget framework used for previous states, which assumes contributions remain fixed as a percentage of revenue. ${ }^{43}$

Figure 20

## Colorado's Projected Assets and Operating Cash Flow

Under fixed 5 percent return scenario and applying the sustainable budget contribution assumption

Note: Assumes actual investment returns of 5 percent and employer contributions are fixed as a percentage of own source revenue (sustainable budget). Sources: The Pew Charitable Trust and The Terry Group, based on publicly available Comprehensive Annual Financial Reports (CAFRs), actuarial reports and valuations, or other public documents, or as provided by plan officials.

[^17]
## Colorado

There is clear evidence that Colorado's fixed-rate funding policy, which sets employer contributions at 19.13 percent of payroll for the state and school divisions, has contributed to Colorado's deteriorating fiscal position. ${ }^{44}$ Between 2000 and 2016, the state's funded ratio fell from over 100 percent to 46 percent, causing the state to drop from $15^{\text {th }}$ to $46^{\text {th }}$ in pension funding across the 50 states. In response to the system's funding crisis, Colorado policymakers adopted legislation in 2010 with the goal of putting these systems on a path to full funding within 30 years. ${ }^{45}$ However, in 2015, an independent consultant hired by the state conducted a stress test analysis on the impacts of the 2010 reforms which projected about a one-in-four chance that, without additional policy intervention, at least two of the PERA plans could face technical insolvency. ${ }^{46}$

The results of our stress test analysis are consistent with this finding as well as a more recent estimate of insolvency risk published by PERA plan actuaries: an estimated 20 percent to 23 percent probability of technical insolvency under current policy for the state and school divisions. ${ }^{47}$ In fact, plan actuaries forecast insolvency for Colorado PERA state and school divisions by 2041 assuming a 5.75 percent return or less, while our projections at a 5 percent rate of return with similar contribution policy assumptions result in asset depletion by 2042.48

The consistent result is not surprising. The estimates of the real return on assets in our capital market assumption model track closely to those supplied by consultants hired by the state (Figure 21). The differences in return distribution between our typical portfolio and Colorado's are driven by asset allocation, a longer projection horizon, and slight differences in expected investment performance and volatility for individual asset classes.

[^18]Figure 21
Colorado's Distribution of Returns Compared with Typical Portfolio under Stochastic Simulation
Typical portfolio has expected return of 6.4 percent compared with Colorado's 7.1 percent

Notes: Labels are for returns at the $10^{\text {th }}, 25^{\text {th }}, 50^{\text {th }}, 75^{\text {th }}$, and $90^{\text {th }}$ percentile. Colorado shows distribution of returns over 40 years with inflation adjusted to 2 percent. Typical portfolio has 51 percent stocks, 27 percent fixed income/cash, and 22 percent in alternatives (i.e. private equity and real estate) and distribution is over 30 years. Sources: The Pew Charitable Trusts, The Terry Group, and Pension Trustee Advisors (October 2015).

Given these results, the state is currently considering additional reforms that would require increased employee and employer contributions as well as cuts to benefits for current employees and retirees. At the time of this writing, a reform bill that includes these changes - as well as a requirement that stress test be performed on a regular basis - is awaiting signature by the Governor. ${ }^{49}$ We estimate that the reform would largely address the insolvency risk issues first identified by the state via stress test analysis.

In fact, Colorado's reform experience over the last decade represents the strongest example to date of applying stress testing simulation to inform pension reform discussions, and validates the findings and central recommendation of this paper.

## Ohio

Like Colorado, Ohio state statute establishes a flat maximum employer contribution rate toward retirement benefits of 14 percent of payroll. However, in contrast to Colorado, the state's current fiscal position is representative of the national average with a 2016 funded ratio of 72 percent. The state's more favorable position compared with Colorado's is largely the result of reforms implemented in 2012 that reduced benefits for both future and current workers - a result of a

[^19]pension legal framework that provides weaker legal protections for worker benefits than other states. ${ }^{50}$ In the year following the reform, Ohio's reported liability fell by over $\$ 9$ billion, the second-largest year-over-year decrease experienced by any state since 2000. ${ }^{51}$

However, in the face of another economic downturn, these reforms may not be adequate to protect Ohio's retirement system. The results under a fixed 5 percent return, sustainable budget scenario show Ohio's funding levels and plan assets declining over time. Indeed, the Ohio Public Employees Retirement System (OPERS) would hit insolvency in 2056 under this scenario, and the Ohio State Teacher Retirement System (STRS) would see funding levels drop from 75 percent funded to 56 percent funded.

Figure 22
Ohio's Projected Assets and Operating Cash Flow
Under the fixed 5 percent return scenario and applying the sustainable budget contribution assumption

Note: Assumes actual investment returns of 5 percent and employer contributions are fixed as a percentage of own source revenue (sustainable budget). Sources: The Pew Charitable Trust and The Terry Group, based on publicly available Comprehensive Annual Financial Reports (CAFRs), actuarial reports and valuations, or other public documents, or as provided by plan officials.

Both Colorado and Ohio have taken measures to address eroding fiscal health; however, neither state has built-in policies to adjust to market downturns or react to changing economic circumstances. If investments fall short in the future, both states could once again face potential insolvency. As demonstrated below with Virginia and South Carolina, adequate actuarial funding policies can be instrumental in maintaining funding in uncertain and volatile investment climates.

[^20]
## Virginia and South Carolina: Impact of Volatility on Costs

In contrast to Colorado and Ohio, Virginia and South Carolina follow actuarial funding policies crafted with the goal of achieving a 100 percent funded ratio by a targeted date, a practice that is typical across most states. This is a primary reason that Virginia and South Carolina face limited risk of fiscal distress over our forecast period under the fixed 5 percent return scenario. However, the results diverge under the asset shock economic scenario, and even more so when more sophisticated stochastic simulation methods are applied.

South Carolina is more at risk of fiscal distress than Virginia given its weaker fiscal position - the state has a funded ratio of only 52 percent, ranking $41^{\text {st }}$ among states. Under an asset shock scenario, this creates a heightened risk of insolvency.

In comparison, Virginia tracks more closely to the national average with a 72 percent funded ratio. As a result, stress test results under both the fixed 5 percent return and asset shock scenarios do not indicate fiscal distress. However, stochastic simulation reveals that Virginia's funding policy could result in significantly higher volatility in required contributions over time.

## Virginia

In Virginia, we see the impact of recent contribution increases in the form of fiscal stability over a range of scenarios, even under the fixed 5 percent return scenario in which the state makes only sustainable budget contributions. Though the state's fiscal position worsens considerably under these conditions - with the funded ratio declining to 62 percent in 2037 - fiscal distress is not evident over the forecast period (Figure 23). ${ }^{52}$ In addition, benefit reforms enacted in 2014, which place new workers in a hybrid retirement plan, mitigate a portion of the increase in employer contributions that would otherwise occur, and will help to make pension costs somewhat more predictable for the state over time.

[^21]Figure 23
Virginia's Projected Unfunded Liability and Funding Levels
Under fixed 5 percent returns scenario and applying the sustainable budget contribution assumption

Note: Assumes actual investment returns of 5 percent and employer contributions are fixed as a percentage of own source revenue (sustainable budget). Sources: The Pew Charitable Trust and The Terry Group, based on publicly available comprehensive annual financial reports, actuarial reports and valuations, other public documents, or as provided by plan officials.

## South Carolina

Results for South Carolina are similar to those of Virginia, except when we introduce the asset shock scenario. Under these conditions, we forecast fiscal distress within 20 years - with assets plummeting by more than two-thirds and the operating cash flow ratio dropping to negative 40 percent (Figure 24). It is important to reinforce that this analysis assumes the state keeps employer contributions stable as a share of own source revenue, which leaves out scheduled increases in contributions based on legislation passed in $2017 .{ }^{53}$ Simulations using the state policy contribution assumption - which includes these increases - are provided in Appendix II, and result in higher asset balances and improved funded ratios relative to those in Figure 24. The results for South Carolina provide another example of how forward-looking stress test analysis can help to ensure that policymakers develop and stick to well-designed funding policies in each annual budget.

[^22]Figure 24

## Introducing Stochastic Analysis

The results above for Virginia and South Carolina are based on deterministic simulations that provide a wealth of information with which to assess the likelihood of fiscal distress (RQ1) and the impact of lower returns (RQ2). However, we must be attentive to the fact that the world does not behave in a deterministic fashion and that swings in the financial markets can also lead to volatility in pension costs. There are two reasons for this: the magnitude and timing of investment shortfalls; and the design of states' contribution policies.

Stochastic modeling allows us to examine both of these factors by simulating thousands of trials that forecast the variations of possible returns on assets and asset classes over time. Figure 25 illustrates the variation in returns in Virginia from three such trials. Each trial has a 20-year return of 6.4 percent (our median capital market assumptions return) but differ in how they get to that point, with gains and losses reflecting the volatility of investment markets.

Figure 25

## Stochastic Projection of Investment Returns for Virginia over a 20-Year Period

Trials averaging 6.4 percent over 20 years show volatility of returns over time

Note: Each line shows the total growth of a dollar in plan assets from investments. By 2036, in all three of the trials, that dollar value is projected to grow by 345 percent for an annual growth rate of 6.4 percent. Sources: The Pew Charitable Trust and The Terry Group, based on publicly available comprehensive annual financial reports, actuarial reports and valuations, other public documents, or as provided by plan officials.

The different paths towards 20-year returns of 6.4 percent provide an illustrative example of financial market volatility based on a consistent set of capital market assumptions, as discussed in the Methodology section. This variation can result in significant swings in annual required contributions, depending on the state's specific funding policy. This variability in cost can best be illustrated by comparing outputs for stochastic and deterministic simulations for the same rate of long-term returns.

For Virginia, we evaluated results based on both rates of return suggested by our capital markets analysis for the state, as well as the plan's assumed rate of 7 percent. Over the next 20 years, total employer contributions for Virginia pension plans are expected to equal 12.4 percent of payroll, if returns are precisely 7 percent (the plan's assumption) each year. In contrast, examining 10 stochastic simulations where investment performance varies each year, shows total contributions over the projection period ranging from 9.1 percent to 18.7 percent of payroll. In other words, costs can increase by as much as 50 percent over the expected 12.4 percent employer contribution rate, under a scenario in which the 20-year assumed rate of return is met, but rates fluctuate year-over-year. Results assuming a 6.4 percent return ( $50^{\text {th }}$ percentile using common capital market assumptions) and 4.9 percent ( $25^{\text {th }}$ percentile) indicate similar levels of contribution volatility for Virginia.

Figure 26
Projected Impact of Volatility of Cost for Virginia Compared with South Carolina
Funding policy has significant impact on range of required contributions

Note: 20-year projected contributions at different returns. Sources: The Pew Charitable Trust and The Terry Group, based on publicly available comprehensive annual financial reports, actuarial reports and valuations, other public documents, or as provided by plan officials.

Stochastic analysis for South Carolina yields a strikingly different result than that for Virginia: the range of possible costs clusters tightly around the employer contribution rate estimated in the deterministic simulation (Figure 26). The primary factor limiting cost volatility in South Carolina is its funding policy. Unlike Virginia, which sets contributions based on the latest actuarial valuation and allows for required payments to either increase or decrease to offset return volatility, South Carolina sets a contribution floor, but otherwise keeps the contribution rate relatively stable. Specifically, the state's funding policy does not automatically adjust contributions downward to account for investment gains unless the plan is fully funded; nor does it adjust them upward to offset investment losses, unless the new funding level falls below the contribution floor. In other words, contribution rates and total contribution amounts are designed to be less volatile.

A key finding of the stochastic analysis is that well-designed funding policy can mitigate much of the cost volatility caused by the amount or timing of investment shortfalls. We conclude that states can, in fact, solve for a fair amount of uncertainty with well-drafted contribution policies. Like South Carolina, states can construct funding policies that explicitly maintain adequate funding levels during good economic times to create a cushion, or surplus, to protect against contribution shortfalls during economic downturns.

## North Carolina and Wisconsin: Policies to Manage Cost and Volatility

Retirement systems in North Carolina and Wisconsin have consistently ranked among the bestfunded public pensions in the U.S., with 2016 reported funded ratios of 88 percent and 99 percent, respectively. ${ }^{54}$ For this reason, North Carolina and Wisconsin are at a minimal risk of fiscal distress. Both have maintained a commitment to fiscal discipline and have enacted policies that strengthen the financial position of their public plans. However, the two states have achieved fiscal health through different paths, which are reflected in different projected results under stochastic analysis.

## North Carolina

North Carolina has maintained its full-funded status through strict adherence to an actuarial funding policy that is much more robust than that of a typical state pension plan. The policy requires that the state increase contributions to offset - or amortize - any increase in the unfunded liability over 12 years using level payments. This compares favorably with the average state amortization period of 25 years or more, and the less restrictive percent of payroll model utilized by other states. More recently, North Carolina also adopted a policy that would steadily increase contributions as a share of payroll for the next 20 or more years, even if investments meet their targets. ${ }^{55}$ Collectively, these policies are projected to result in annual increases in state contributions averaging 4.9 percent over 20 years. If state policymakers follow this policy and the state achieves the target rate of return, North Carolina could expect a surplus of about $\$ 61$ billion by 2037, making the state particularly well suited to withstand economic downturns.

Even in the absence of adherence to these strict contribution policies, under the sustainable budget assumption - in which contributions are projected to only increase at the same rate as revenues - North Carolina would not be at risk of insolvency under a fixed 5 percent return scenario. Under these conditions, we project that the state's funded ratio would drop to approximately 70 percent over 20 years, with unfunded liabilities increasing by $\$ 30$ billion over that time frame. Yet, such an outcome would very likely still place North Carolina among the bestfunded states under that scenario. This result provides further evidence that setting and following a well-designed contribution policy is one of a state's best protections against fiscal distress and cost volatility in the future.

However, the potential for unaffordable increases under the state policy contribution assumption is more pronounced relative to that of other states we've examined, as demonstrated by the results of stochastic simulation. For example, looking at 10 trials with returns that average over 20 years to the plan's expected return of 7.2 percent, North Carolina's costs range from 14 to 19 percent of payroll, with an average contribution rate of 16 percent. The results when assuming 6 percent returns (50th percentile using North Carolina's asset

[^23]allocation and our capital market assumptions), and at a lower return of 4.6 percent (25th percentile), show an even broader range of outcomes than those based on deterministic projections (Figure 27).

Figure 27
Projected Impact of Volatility of Cost for North Carolina Compared with Wisconsin
Risk-sharing provisions limit cost volatility for Wisconsin

Note: 20-year projected contributions at different returns. Sources: The Pew Charitable Trust and The Terry Group, based on publicly available comprehensive annual financial reports, actuarial reports and valuations, other public documents, or as provided by plan officials.

For policymakers in North Carolina, the challenge is how to address the potential for unaffordable spikes in cost resulting from market volatility. In all 10 of the stochastic simulation trials at the 50th percentile, and in most of the trials at the 25th percentile, North Carolina's pension plan reaches full funding under the state's current funding policy. However, employer contributions could rise to more than 20 percent of payroll, nearly double the state's current contribution rate of 10 percent.

## Wisconsin

Wisconsin has also demonstrated a commitment to making full actuarial contributions by following a funding policy that calls for addressing unfunded liabilities more quickly than most states. ${ }^{56}$ In addition, the state's unique risk-managed defined benefit plan mitigates most of taxpayers' exposure to market fluctuations. Specifically, the plan adjusts employee contributions to account for unplanned costs, as well as sharing gains if investments outperform. The plan also increases and decreases its post-retirement annuity benefits based on returns and funding status. ${ }^{57}$

[^24]Under a fixed 5 percent scenario, we estimate that approximately 75 percent of costs associated with lower investment returns are accounted for through this innovative plan design. Given these risk-sharing provisions, cost uncertainty for Wisconsin's state budget is muted in relation to North Carolina. Additionally, even after 20 years of fixed 5 percent returns and the sustainable budget assumption, Wisconsin remains relatively well funded at over 85 percent.

Stochastic analysis further illuminates this divergence. Wisconsin is expected to have both lower costs and volatility of costs over the next 20 years when compared with North Carolina (Figure 27). Across the trials shown, employer costs for Wisconsin can vary by as much as 4.7 percent of payroll over the 20-year projection. In contrast, North Carolina taxpayers could face contribution requirements that vary by almost 10 percent of payroll - or approximately 3.2 percent of state revenue - depending on the timing and volatility of returns. North Carolina shows that a strong contribution policy can ensure the plan is well funded, while Wisconsin shows that cost-sharing policies designed to mitigate risk can make costs more predictable.

The efficacy of risk-management policies in Wisconsin are further reflected in the detailed results for all simulations included in Appendix II. The state's results across our metrics are striking. For example, the employer contribution rate does not exceed 25 percent of payroll in virtually any year under any simulation; and the funding level drops below 80 percent in any forecasted year in less than half of the simulations. Additionally, the largest year-over-year increase in contribution rates across any of the 10,000 simulations we modeled under state policy was less than 4 percent of payroll. However, Wisconsin's policy does result in more variable outcomes for workers - employee contributions will rise or fall depending on plan funding, and investment performance will determine the size of COLAs provided to retirees, or whether COLAs are provided at all.

Although pension funds in aggregate face a tougher challenge now than ever before, North Carolina and Wisconsin demonstrate how, through different policies, states can maintain affordable pension systems with more predictable costs. The results for North Carolina also demonstrate how stress testing can aid policymakers in states with well-funded pension plans by identifying the risks associated with financial market volatility and potential improvements to even the strongest pension funding policies.

## IV. Conclusion and Recommendations

The current fiscal position and outlook for state pension systems warrant careful attention. Our analysis demonstrates how vulnerable many state pension systems are to an economic downturn or extended period of low investment returns.

We conclude that states like New Jersey and Kentucky, which are severely underfunded, are at high risk of insolvency. Meanwhile, Connecticut, Pennsylvania, and other states that have undergone pension reforms are better protected against total insolvency, but are likely to experience high fixed costs over the long term. States without adequate funding policies, like Colorado and Ohio, are also at risk of fiscal distress and face the greatest uncertainty around how they will manage volatile financial markets given their fixed-rate funding policies. In effect, these states do not have a plan in place to manage through an economic downturn.

Conversely, states like Virginia and South Carolina, which have actuarial funding policies that adjust in response to lower- or higher-than-expected investment returns, may fare better during periods of market distress, but only if they meet their contribution targets each year. Even for well-funded states with robust policies, like North Carolina, it is unclear if they can fully adhere to those policies during particularly difficult economic periods. Finally, Wisconsin - by designing its pension plan with significant risk-sharing elements in addition to a strong funding policy serves as an exemplar for managing cost volatility under virtually any scenario.

Traditionally, researchers pointed to aggregate measures such as total unfunded liabilities as a means of assessing the fiscal health of U.S. public pensions, and debate centered on the proper set of assumptions, including discount rates, to accurately calculate this figure. However, we find cash-flow-driven metrics to be more useful as indicators of potential fiscal distress, and that stress test simulation based on comprehensive assumptions to be a more appropriate assessment method.

In contrast with current reporting practices, stress testing allows states to better assess the likelihood of fiscal distress, the potential for permanent high costs, and the effects of market volatility and contribution policies. We find stress test results that are evaluated in relation to state revenues or payroll provide an intuitive benchmark with which to assess costs. In addition, we demonstrate that an analytic framework that includes only the risk of investment shortfalls is inadequate without also simulating a range of contribution behaviors.

We find three key benefits to stress testing, generally:

- First, stress testing can aid administrators and policymakers in planning for the next downturn, as well as protect state plans against the worst possible outcome: insolvency.
- Second, stress testing provides a fuller understanding of the impacts caused by market fluctuations and can inform good funding policies and practices to better manage volatility and ultimately lower costs.
- Finally, stress testing can provide a useful tool for considering a range of possible economic scenarios when scoring proposed reforms.

The lessons learned in this analysis also apply to the 40 states not examined here. As described at the outset, we selected 10 states from across the country to provide a realistic distribution of policies and fiscal positions. Although this allows us to highlight a myriad of different causes and potential solutions to the fiscal challenges state systems face, it also drives home a much simpler and universal conclusion from our research: Stress testing should be a standard reporting practice for all public retirement systems.

## Historical Background: Public Pensions Vulnerable to Next Economic Downturn

 In aggregate, state and local pension systems have never been more exposed to market volatility, based on fiscal measures and economic outlook- State and local governments report a larger total pension debt in both absolute terms and as a share of U.S. GDP than any time before the Great Recession (Figure A).
- Pension costs have nearly doubled as a percentage of available state revenue since 2001, when the pension deficit reported by state and local governments in aggregate was approximately zero (Figure B).
- Since the early 1990s, measures of investment risk for pension portfolios have more than tripled, as has the use of higher cost alternative investments, including real estate, private equity, and hedge funds (Figure C).
- As the population ages, and larger shares of public pension plan participants move into retirement, benefit payments will take up a growing share of plan assets and states funds will be less able to absorb unexpected costs and investment shortfalls (Figure D).

## Definitions and Terms

Actuarial required contribution or annual required contribution (ARC): Using plans' own economic and demographic assumptions, the ARC calculation includes the expected cost of benefits earned for the current year and an amount to reduce some of the unfunded liability. Under prior rules, the ARC calculation included in governmental financial statements had to conform to the Governmental Accounting Standards Board's (GASB) regulations, but it is no longer a required disclosure.

Actuarially determined contribution (ADC): A contribution requirement for plan sponsors set by each plan based on actuarial methods and practices. The ADC does not have to comply with the minimum standards used in calculating the actuarially required contribution as defined by the Government Accounting Standards Board (GASB).

Alternative investments: Although there is no fixed definition for alternative investments, they are generally agreed to include private equity, hedge funds, real estate, and some commodities. These investments typically lack an established public exchange, have low liquidity, and can be more difficult to value. Alternative investments usually carry higher fees and can be used to diversify investment portfolios or to achieve higher rates of return, although often at higher levels of risk.

Amortization policy: Rules for how actuaries calculate the amortization period when computing the ARC. Key parameters are how long the employer must pay off the debt (often 30 years), when payments are level or back-loaded (level dollar or level percentage of payroll), and whether the amortization period shrinks each year or resets annually (closed versus open).

Amortize: Make scheduled payments to eliminate pension liabilities over specific period.

Asset allocation: The distribution of assets under management and typically invested by designated asset classes, such as equities, fixed income, or alternatives (which include private equity, real estate, and other complex financial instruments).

Assets: Money on hand to fund benefits. Assets build up over time, generally from three sources: employee contributions, employer contributions, and investment returns. Some plans use actuarial smoothing to acknowledge only unexpected investment gains and losses over a given period - usually five years. Those plans present an actuarial value of assets as opposed to a market value of assets.

Asset shock scenario: Economic scenario used in Pew's stress test analysis that incorporates an initial adverse shock followed by low returns over the long term. The scenario is based on the Federal Reserve's scenarios for stress testing under the Dodd-Frank Act.

Assumed rate of return: The assumed, or expected, rate of return is the investment return target and the result that a pension plan estimates its investment allocation mix will deliver.

Basis point: A commonly used unit of measure (one one-hundredth of one percentage point) of the change in the value of a financial instrument.

Bonds: An instrument of indebtedness of the bond issuer to the holders. It is a debt security, under which the issuer owes the holders a debt and, depending on the terms of the bond, is obliged to pay them interest (the coupon) and/or to repay the principal at a later date, termed the maturity date.

Cash equivalents and short-term investments: Financial investments of relatively short duration that generally present low risk and lower returns but are more liquid than other investments. For pension plans, these can be notes or certificates of deposit.

Cash flow (measures): Metrics used specifically in this analysis, based on the difference between contributions and benefits (operating cash flow) and applied mainly as an early indicator of long-term fiscal solvency. For most public plans, this number will be negative, highlighting how actuarial funding and the maturity of plan demographics leave pension funds dependent on investment returns to maintain asset levels.

Cost-of-living adjustment (COLA): Annual increases to retirees' benefits to help mitigate the effects of inflation. COLAs were historically provided in many public-sector DB plans. They can be fixed increases or based on the consumer price index (CPI) to keep pace with inflation.

Defined benefit (DB) plan: A plan in which the employer promises a specific amount of monthly retirement income based on a formula that typically considers the employee's salary, years of service, and age.

Defined contribution (DC) plan: A plan that provides employees with an individual retirement account that grows through investment of accumulated employer and employee contributions. Annual returns are generally based on investment performance and are not typically guaranteed. DC plans can provide workers with access to annuities upon retirement.

Deterministic simulation: Simulation used in Pew's stress test analysis to illustrate how portfolios perform under precise circumstances of our own design, typically by performing a single trial run for each year in the forecast that strictly adheres to the same user-specified assumptions on investment returns and economic metrics.

Equities: Stocks held by investors that represent ownership in a piece of a company. They can be domestic or international. Equities do not guarantee a specific rate of return and thus are generally riskier than fixedincome investments. But equities also have the potential for higher returns, and shareholders' investments may grow rapidly with the market.

Fixed 5 percent returns scenario: Scenario applied to Pew's stress test analysis that uses a low rate of return over an entire forecast period. The purpose of this scenario is to assess how plans perform when investment returns are lower than expected over the long term.

Fixed income: Investments in which returns are predictable and paid at designated times. These can include domestic or international bonds. Because fixed-income investments generate predictable streams of income, they are generally considered low risk.

Funded ratio: The level of assets at market value in proportion to accrued pension liability. This is an annual point-in-time measure, as of the valuation date.

Gross domestic product (GDP): The total value of goods produced and services provided in a country during one year. GDP is usually calculated on an annual basis.

Gross state product (GSP): The total annual value of a state's output.

Hedge fund: A relatively unregulated private investment fund or pool that trades and invests in various risky assets such as securities, commodities, currency, and derivatives. Available only to sophisticated investors with
significant assets, hedge funds employ several different strategies to earn high returns (either in an absolute sense or over a specified market benchmark) for investors and may be used to diversify a portfolio.

Hybrid retirement plan: A plan that combines a defined benefit based on the employee's final average salary with a separate defined contribution savings account.

Investment fees: Any fees that a pension plan pays to professionals to allocate its assets. These can be administrative or money management fees. Generally, more traditional investment types have lower investment fees than more complex investments.

Liabilities: Total value of pension benefits owed to current and retired employees or dependents based on past years of service; sometimes referred to as the Actuarial Accrued Liability (AAL).

Net amortization: Measures whether total contributions to a public retirement system would have been sufficient to reduce unfunded liabilities if all actuarial assumptions - primarily investment expectations - had been met for that year. The calculation uses the plan's own reported numbers and assumptions about investment returns. Plans that consistently fall short of this benchmark can expect to see the gap between the liability for promised benefits and available funds grow over time.

Net pension liability: Current-year pension debt calculated as the difference between the total value of pension benefits owed to current and retired employees or dependents and the plan assets on hand. Pension plans with assets greater than accrued liabilities show a surplus.

Normal cost: The cost of benefits earned by employees in any given year. Also called service cost.

Own source revenue (OSR): Revenues raised directly by state and local governments, generally excluding funds from the federal government.

Pay-as-you-go: Contributions pay for benefits as they come due, rather than pre-funding benefits as they are earned.

Pension debt/unfunded liabilities: The difference between the total value of pension benefits owed to current and retired employees or dependents and the plan assets on hand. This is an unfunded obligation for past service. The data reflect the GASB standards in effect at the time. Before 2014, the data represent the unfunded actuarial accrued liability. In 2014 and after, this is reported as the net pension liability. Pension plans with assets greater than accrued liabilities show a surplus.

Private equity: An asset class consisting of equity securities and debt in operating companies that are not publicly traded on a stock exchange.

Real assets: Physical or tangible assets, such as precious metals, commodities, or oil, as opposed to financial assets.

Risk premium: The amount the return on a risky asset is expected to exceed the risk-free rate. This premium can be thought of as compensation for the investor taking on risk.

Sensitivity analysis: A method for measuring the impact of differing assumptions, particularly around investments, on key pension funding measures. Sensitivity analysis showing an investment return assumption 1 percentage point higher or lower than the base assumption is included in the GASB disclosures.

State policy (behavioral) assumption: Condition applied to Pew's stress test analysis that assumes strict adherence to current actuarial funding requirements based on states' written contribution policy.

Stochastic simulations: Simulations used in Pew's stress test analysis that model the probabilities of various financial outcomes given specified means and standard deviations of economic variables and market returns. Our stress test model generates 10,000 runs for each simulation, which yields a distribution of investment returns for each year.

Sustainable budget (behavioral) assumption: Condition applied to Pew's stress test analysis that assumes contributions are set at a fixed percentage of state revenue. The assumption tracks closely with what states currently expect to contribute to their pension systems, if all plan assumptions are met. The sustainable budget assumption implicitly sets a limit on what is affordable so as not to place strain on the budget at a time when other state obligations may also require increases in funding.

Tolerance for payment: Measure used in Pew's stress test analysis that assumes that policymakers will be willing to increase payments over a 10-year period, measured as a percentage of revenue, by the same amount as payments have increased since the year 2000.

Unfunded actuarial accrued liability (UAAL): See Pension debt.

Volatility: Investment volatility measures how much the value of a particular asset class or a portfolio in total moves up and down with financial markets and the economy. It is the standard measure of risk based on historical results and is also used as a forward-looking indicator of risk. A higher volatility indicates the potential for larger fluctuations in value or price.

Yield: The return on an investment. In securities, it is the dividends or interest received, usually expressed as an annual percentage of either the current market value or the cost of the investment.

## Appendices

This technical appendix is divided into two sections. Appendix I contains supporting detail for the methodology applied to develop model inputs for actuarial assumptions, own source revenue, and capital market assumptions. Appendix II includes comprehensive financial outputs from the model for each state in our study, including: balance sheet, payment/contribution, and cash flow metrics. These financial outputs are provided for years 5, 10, and 20 for each economic scenario in our model. Additionally, 30-year baseline projections, using the plans' own assumptions, are also included in Appendix II.

Specifically, the model inputs detailed in Appendix I include:

- Actuarial assumptions: This first section of Appendix I describes how the plans' actuarial assumptions are used by the stress test simulation model to forecast pension benefits, costs, and liabilities. This approach was designed to reflect the most detailed information available from experts in each state, and to create a baseline that closely aligns with each state's forecast.
- Own source revenue: The methodology for forecasting own source revenue, based on expected growth in gross state product, is explained in section three and makes note of certain limitations for comparing this measure of budget capacity across states. We note here that each state has reported revenues for fiscal years 2016 and 2017 that are more current than the inputs used in the stress test simulation model and, in most cases, publish short-term to medium-term annual estimates of state revenue growth. The inputs to the simulation model are based on the most current information available from the U.S. Census Bureau and are designed to provide a long-term benchmark for budget capacity, as opposed to a precise estimate of tax revenue for any given state.
- Capital market assumptions: Section two describes our investment return assumptions, which align closely with expected rates of return recently developed by market experts. On average, pension funds have posted 5-, 10-, and 20-year returns, gross of fees, of 7.11, 5.98 , and 7.34 percent, respectively. ${ }^{58}$ Although the fixed 5 percent return scenario used in the model is lower than plans' current assumptions as well as these historical rates, we wanted to use the best forward-looking information available and to demonstrate lower return scenarios consistent with the primary purpose of stress test analysis. The output for each state does include results at assumed rates of return, as well as higher returns, including a fixed 9 percent scenario.

[^25]The model outputs are grouped together for each state in Appendix II and include:

- Baseline projections for each state: These 30 -year baseline projections provide a combined forecast for the plans in each state we examined, based on the plans' own assumptions and expected returns. The projections include long-term outlooks for the same fiscal metrics provided by the model output at years 5,10 , and 20.
- Plan assumptions: These tables detail each individual plan's actuarial assumptions, as reported in annual reports, actuarial valuations, or documents provided by plan administrators.
- Fiscal metrics: The stress test simulation model summarizes results using a comprehensive set of actuarial, economic, and financial accounting metrics. These include standard balance sheet, payment and contribution, and cash flow metrics that assess fiscal health over time and provide indicators of future fiscal challenges under a variety of economic and behavioral scenarios.
- State analysis graphics: A standard suite of four graphics is provided for each state and summarizes key results for deterministic simulation under the fixed 5 percent return scenario and, where applicable, the asset shock scenario.

A note on supplemental analysis: The discussion of Pennsylvania and Connecticut refers to projections beyond the 30-year forecast period, as well as the impact of recent reforms on our forecast. In both cases, we project that under the fixed 5 percent return scenario, unfunded liabilities will persist well beyond a 30 -year time horizon - as long as 50 years in total - when also including historical results. For both states, we also estimate lower costs that can be attributed to recent reforms that establish a hybrid plan for new workers. The details of these analyses, although not included in the appendix, are available upon request.

All pension plan projections and other analysis herein are based on the best information available. In certain cases, this may include updated assumptions or other information published or provided by the individual pension plans that are included in our study.

## Appendix I

Model Inputs

## Actuarial Assumptions

MuniSage is a software application that can forecast municipal, county, and state budgets, populations, revenues, and demographics. Below is documentation from The Terry Group for the actuarial assumptions applied to the stress test simulation model using MuniSage.

## Basic notations and variables

Normal cost at time $t: N C_{t}$
Payroll at time $t: P_{t}$
Benefit payment at time $t: B P_{t}$
Actuarial accrued liability at time $t$ : $A A L_{t}$
Actual inflation at time $t:$ ActInf $_{t}$
Expected inflation: ExpInf
Discount rate (interest rate): $i$
Survival from time $t$-1 to time $t$ : $S_{t}$
Expected COLA: ExpCOLA
Actual COLA at time $t: \operatorname{ActCOLA} A_{t}$

## Relationship between payroll, normal costs, benefit payments, and liabilities

The main method MuniSage uses to project payroll is to increase payroll each year with a payroll growth rate:

$$
P_{t}=P_{t-1} \cdot g_{t}
$$

where $g_{t}$ is the payroll growth rate.
Normal costs are usually expressed as a normal cost rate times payroll:

$$
N C_{t}=N \text { CRate }_{t} \cdot P_{t}
$$

where NCRate $_{t}$ is the normal cost rate at time t .
The actuarial accrued liability AAL is projected via the roll-forward formula:

$$
A A L_{t}=A A L_{t-1} \cdot(1+i)+N C_{t-1} \cdot(1+i)^{0.5}-B P_{t} \cdot(1+i)^{0.5}
$$

Normal costs and benefit payments are assumed to occur at the middle of the year.

## How payroll projection is affected by inflation

MuniSage models the effect of actual inflation on payroll by adjusting the payroll growth rate by a portion of unexpected inflation. Because the payroll growth rate has an expected inflation component
built in, the adjustment due to actual inflation is based on the difference between actual inflation and expected inflation, not based on the actual inflation itself.

Payroll growth typically does not respond to actual inflation immediately. To reflect the "stickiness" of payroll growth to actual inflation, MuniSage uses the following parameters to model how quickly payroll growth responds to inflation.

Lag : a variable that specifies the lag between actual inflation and payroll growth rate

AvgPeriod: the averaging period for inflation, i.e., actual inflation from multiple prior periods are averaged for determining the effect of actual inflation on payroll growth

Inf Sens: an inflation sensitivity factor that takes into account the percentage of unexpected inflation that is reflected in the payroll growth. A factor of less than $100 \%$ reflects the belief that the employers and employees do not believe the unexpected inflation to continue into the future

StaPeriod: the stability period where inflation adjustment is assumed to stay the same.

A typical application of these parameters will be a three-year bargaining cycle. In this case the average inflation over the prior three years will be used in the payroll growth of the next three years. The parameters can be set as Lag = 1 , AvgPeriod $=3$, InfSens $=100 \%$, and StaPeriod $=3$. If it is desired to reflect inflation on payroll growth immediately, the parameters can be set as Lag = 1, AvgPeriod = 1, InfSens $=100 \%$, and StaPeriod $=1$.

We define average inflation as the actual inflation averaged over prior periods:

$$
\operatorname{AvgIn} f_{t}=\frac{1}{\text { AvgPeriod }} \sum_{j=0}^{\text {AvgPeriod }} \operatorname{ActIn}_{t-L a g-j}^{-1}
$$

Then inflation adjustment is defined as

$$
\text { InflationAdj } j_{t}=\left(A v g \operatorname{Inf} f_{t}-\operatorname{ExpInf}\right) \cdot \operatorname{InfSen}+1
$$

The projection of payroll will be modified as

$$
P_{t}=P_{t-1} \cdot g_{t} \cdot \text { InflationAdj } j_{t}
$$

## How normal cost is affected by inflation

Normal costs are affected by actual inflation via payroll. Thus, the equation

$$
N C_{t}=N C \text { Rate }_{t} \cdot P_{t}
$$

is the same, but the normal costs will change if payroll reflects actual inflation.

Note that the normal cost rate is not changed. The normal cost rate will change if the valuation assumptions change, i.e., if the expected inflation change. MuniSage reflects the effect of actual
inflation on payroll, but it does not model changing valuation assumptions and changing inflation expectations.

## How AAL is affected by inflation

Actual inflation affects actuarial accrued liabilities via its effect on normal costs and the roll-forward formula.

Additionally, the actual payroll growth being different from the expected payroll growth will create liability gains and losses. MuniSage models these liability gains or losses by multiplying the active portion of the actuarial accrued liability by the payroll inflation adjustment factor.

ActPercent: Percentage of the actuarial accrued liability that is assumed to be active, an input to MuniSage

InflationAdj $j_{t}$ : Payroll inflation adjustment factor, defined in the payroll section above

Then the actuarial accrued liability is projected using the following formula

$$
\begin{gathered}
A A L_{t}=\left[A A L_{t-1} \cdot(1+i)+N C_{t-1} \cdot(1+i)^{0.5}-B P_{t} \cdot(1+i)^{0.5}\right] \cdot \\
{\left[1+\left(\text { InflationAdj }_{t}-1\right) \cdot \text { ActPercent }\right]}
\end{gathered}
$$

## How MuniSage models COLA policy

A typical COLA policy responds to inflation with a minimum COLA, a maximum COLA, and a transition between the minimum and the maximum. See the chart below. The minimum COLA can be $0 \%$ if the COLA policy does not have a minimum. The maximum COLA can also be set to be a large number if the maximum COLA does not apply.

MuniSage uses four parameters to specify a COLA policy:

MinCOLA: minimum COLA

## MaxCOLA: COLA cap

ExcessPoint: the point from which the COLA transitions from minimum to maximum
PercentInf: the percentage of actual inflation reflected in the COLA, i.e., the slope of the transition line in the chart above

Then actual annual COLA is modeled as

$$
\text { ActCOLA }_{t}=\min \left(\text { MaxCOLA, MinCOLA }+\max \left(0, \text { ActInf }_{t-1}-\text { ExcessPoint }\right) \cdot \text { PercentInf }\right)
$$

## How inflation affect benefit payments

MuniSage models the impact of inflation on benefit payments through the realized COLA. If there is no COLA, then the benefit payment is not affected by COLA.

First, benefit payments are split into separate payment streams based on payment year ("benefit payment triangle"). Let $B P_{t, d}$ denote the benefit payment stream starting in time $t$, after $d$ years. The first-year benefit payment for the payment stream that begins in year $t$ is calculated as the total benefit payment at time $t$ minus the payment streams from prior years.

$$
B P_{t, 1}=B P_{t}-\sum_{j=1} B P_{t-j, j+1}
$$

The payment stream starting in time $t$ includes lump sums and refunds that would not continue to the second year and, therefore, would not be subject to COLA. So the payment in the second year for the benefit payment stream starting in year $t$ should be reduced by a factor that represents lump sums and refunds. Additionally, the benefit payment will be reduced by mortality, and increased by COLA built into the valuation assumption. Thus, we calculate the second-year benefit payment for the benefit payment stream starting in time $t$ by

$$
B P_{t, 2}=\left(B P_{t, 1}-(1-\operatorname{PercentCOLA}) \cdot B P_{t}\right) \cdot S_{t+1} \cdot(1+\text { ExpCOLA })
$$

PercentCOLA is an input to MuniSage and specifies the percent of the total benefit payment in year $t$ that is subject to COLA. So $(1-$ PercentCOLA $) \cdot B P_{t}$ represents lump sums and refunds that will not continue to the second year. The survival probability $S_{t}$ used in MuniSage is based on RP2000 50/50 male/female without pre-55 mortality. ExpCOLA is an input to MuniSage and represents the expected COLA in the actuarial assumption.

After the second year, the benefit payment is given by

$$
B P_{t, d}=B P_{t, d-1} \cdot S_{t+d-1} \cdot(1+\operatorname{Exp} C O L A)
$$

Finally, after the benefit payments are split into a benefit payment triangle, the benefit payments are adjusted by actual COLA as they are realized. We back out the expected COLA and replace it with actual COLA.

$$
\begin{gathered}
B P_{t-j, k}=\frac{B P_{t-j, k}}{1+\operatorname{Exp} C O L A} *\left(1+\text { ActCOLA }_{t}\right), j \geq 1, k \geq j+1 \\
B P_{t}=\sum_{j=1} B P_{t-j, j+1}
\end{gathered}
$$

## The impact of COLA on actuarial accrued liability

When the benefit payments change with actual COLA, there will be liability gains and losses when the actual COLA differs from expected COLA. MuniSage calculates the present value of benefit payments before and after COLA adjustment and adds the difference to AAL as liability gains/losses.

## Modeling employer's contribution policy

MuniSage models employer contributions with the following steps:

1. A "funding valuation" is performed at the end of each year. The funding valuation produces two employer contribution components:
a. Regular employer contributions, usually based on the actuarial determined employer contributions (ADEC). If the system does not have an actuarial funding policy, then the funding valuation will calculate according to the funding policy, for example, a statutory contribution rate.
b. Other employer contributions, such as special contribution rates under a certain funded ratio.
2. For each year of the forecast, MuniSage first looks for contribution overrides. If contribution override exists for that year, MuniSage will use the override amount as the employer contribution and skip the rest of the calculations.
3. If there is no contribution override for the year, MuniSage first calculates the employer contributions (regular and other) taking into account the lag between the timing of funding valuations and actual contributions.

## Own Source Revenue

We statistically imputed a stream of projected own source revenue using state GSP forecasts obtained from Moody's Economy.com for each state and a simple linear time series model. We tested several model specifications, including using state personal income (SPI) instead of GSP, but we find that growth in own source revenues is best projected using the simple state-specific model:

$$
\ln \left(\text { OSR }_{i}\right)=\alpha+\beta_{1} \ln \left(G S P_{i}\right)+\beta_{2} \text { unemployment-rate }{ }_{i}+\varepsilon_{i}
$$

where the $\ln (\mathrm{OSR})$ is the natural log of state own source revenue. The independent variables are the natural $\log$ of nominal state GSP $(\ln (G S P))$, and unemployment rate, all by year.

Data on own source revenue come from the Census' Annual Survey of State Government Finance. Own source revenue is a standard benchmark for state budget capacity. General own source revenue excludes intergovernmental transfers (all dollars received from federal and local governments as grants, shared taxes, or loans) as well as revenues from state-operated liquor stores, utilities, and social insurance trusts (including pension system trusts). A limitation of own source revenue is that it includes some revenue sources that states are unlikely to use to pay for pension liabilities, such as tuition fees at state universities. ${ }^{59}$ As a result, our model may slightly understate pension costs relative to state resources. We use data from 1996-2016, as those are the years for which data are available for all variables. State GDP, or gross state product (GSP), is a measurement of the economic output of a state. It is measured by the sum of all value added by industries within the state. It is produced by the Bureau of Economic Analysis and was compiled by Moody's Analytics for its data subscribers. In addition to historical GSP, Moody's projected these data forward to 2047. As with revenue, we used the natural log transformation of GSP in the regression model.

The OSR growth rate for 2015 and 2016, highlighted in green, represent actual year-over-year changes as reported from the U.S. Census Bureau's Survey of State Government Finance. Model estimates are used to project OSR for three years (2017-2019) and are highlighted in orange. After 2019, we assume OSR will grow at the same rate as GSP (highlighted in purple).

[^26]Table 1. Nominal Year-over-Year Growth in Own Source Revenue, 2015-2046

|  | CO | CT | KY | NJ | NC | OH | PA | SC | VA | WI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2015 | 20.1\% | 1.3\% | 3.7\% | 5.3\% | 7.6\% | 4.1\% | 6.6\% | 5.3\% | 8.6\% | 3.7\% |
| 2016 | -10.2\% | -4.5\% | 3.5\% | 0.8\% | 4.6\% | 4.4\% | 3.5\% | 2.3\% | 3.1\% | 5.4\% |
| 2017 | 6.4\% | 1.1\% | 4.0\% | 3.2\% | 4.4\% | 4.9\% | 4.0\% | 4.9\% | 4.4\% | 3.4\% |

## Capital Market Assumptions

Our capital market assumptions contain projections for a variety of financial and economic variables over time. Some of these variables pertain to the broad state of U.S. economic development, such as real GDP and inflation. The rest of the indicators measure the performance of various asset classes, including public equity (both U.S. and non-U.S.), real estate, and private equity returns. Returns are compounded and presented in nominal terms.

Based on our review of various sources of inflation expectation data and the 30-year time horizon of these assumptions, we selected an inflation expectation of $2.0 \%$. The growth of the real gross domestic product (GDP) is a key economic indicator. In its most recent forecast, the CBO projects real GDP growth to average $1.9 \%$ over the next 10 years. Growth in 2017 is projected to be $2.3 \%$, followed by two years at $1.6 \%$, then reverting to the ultimate expectation of $1.9 \% .{ }^{60}$ We assume an average of $2.0 \%$ for growth of real GDP.

The CBO forecasts the ultimate expected rate for 3-month Treasury bills to be 2.8\% and 10-year Treasury notes to be $3.6 \%$ by 2023. We follow expectations built into the CBO forecasts, developing expected returns for fixed income asset classes in a manner consistent with our assumption on the rising rates environment and appropriate durations. For each class, we started with the current yield (as of December 31, 2016) and assumed a five-year transition to the long-term equilibrium yield, with the returns being made up of "coupon" or income return and "price change" (due to the movements in yields).

Source: 2017 CBO Report.

We developed our expected returns for the broad equity asset classes by utilizing a variety of models, as well as reviewing information from actuarial and investment firms. We benchmark this class to the S\&P 500 Index and factor in results from the multistage dividend discount model (DDM). We selected a geometric expected return for U.S. equity class at $6.7 \%$. The historical record, going back to 1970, is supportive of the view that there is no expectation of non-U.S. equity outperforming U.S. equity in the long term. We expect the geometric return for the non-U.S. equity broad asset class will be the same as that for the U.S. equity class.

For Private Equity, we set an illiquidity premium assumption at $1.9 \%$. This is supported by capital asset pricing model (CAPM) regression analysis we performed relating the private equity quarterly historical

[^27]return time series to the analogous public equity returns. To correct for the inherent smoothness within the PE historical returns time series, we regressed PE returns against public equity returns time series with lags of $0,1,2,3$, and 4 quarters. Regression was done on excess returns over the Long-Term Government Bond returns (which we used as a proxy for the long-term "risk-free" rate). We used the same model to calculate the standard deviation for the PE class at $21.1 \%$, assuming a $16.4 \%$ standard deviation for public equity and 0.7 correlation between private and public equities (calculated based on historical analysis).

For real estate, we employ a forward-looking cash flow discount model, much like in the case of U.S. equity. Over a long-term holding horizon, RE returns are primarily driven by dividend yields and NOI growth. ${ }^{61}$ We selected an expected return of $6.0 \%$ for the RE asset class. For this class, the estimate of the risk (e.g. standard deviation) does not rely on historical analysis but rather on a target Sharpe ratio of about 0.36.

For most classes, we utilize monthly and quarterly data to estimate standard deviations and correlations, with an exception of the real estate and the private equity classes, for which only quarterly data are available. We develop the correlation matrix directly from the quarterly or annual data, as appropriate for the most recent 27 years, since 1990, with slight modifications to reflect common sense and consensus among investment firms. Modifications were made to the cash and core bond classes, reflecting correlation for longer periods or other adjustments. The resulting correlation matrix is shown below in Table 2.

Table 2

|  | Expected <br> Geometric <br> Return | Standard <br> Deviation | U.S. <br> Equity | non- <br> U.S. <br> Equity | Cash | Core | Long <br> Gov't | RE | PE |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| U.S. Equity | $6.70 \%$ | $16.4 \%$ | 1.00 | 0.83 | 0.02 | 0.14 | -0.31 | 0.13 | 0.72 |
| non-U.S. Equity | $6.70 \%$ | $18.5 \%$ | 0.83 | 1.00 | 0.03 | 0.14 | -0.28 | 0.12 | 0.66 |
| Cash | $1.70 \%$ | $0.8 \%$ | 0.02 | 0.03 | 1.00 | 0.07 | 0.05 | 0.01 | 0.09 |

The capital market assumptions were modified slightly for the deterministic scenarios. In the fixed 5 percent return scenario (called the "Low Return" scenario in Appendix II), all asset classes are set to return 5 percent for the entire projected period. Similarly, the "High Return" scenario applied a fixed 9 percent return for all asset classes, and the "Current Plan Assumptions" scenario assumed that returns would equal the plan's assumed rate of return for all years.

The "low-for-long" and "asset shock" scenarios applied 12 economic, asset price, and interest rate variables uniformly across all plans. They varied by year for years 1-5, 6-10, and 11-20 of the projection. The specific assumptions for each scenario are outlined in the tables below.

[^28]Table 3
Low-for-Long Scenario

Note: Dollar Figures in Millions

Fixed 5\% Economic Scenario
Public Employees' Retirement Association - State and School

Assets vs. Cash Flow
Assuming 5\% returns and contributions fixed as \% of OSR

Unfunded Liability vs. Funding Levels

## Assuming 5\% returns and contributions fixed as \% of OSR

$\square$ Unfunded Liability (Market Value) $\quad$ Funded Ratio

Total Contributions vs. Benefit Payments Assuming 5\% returns and contributions fixed as \% of OSR

Employer Contributions vs. Pension Debt
Assuming 5\% returns and plans' statutory contribution policy

Pension Debt as Share of OSR Employer Contribution Rate

Asset Shock Economic Scenario
Public Employees' Retirement Association - State and School

Assets vs. Cash Flow
Assuming asset shock and contributions fixed as \% of OSR

Unfunded Liability vs. Funding Levels
Assuming asset shock and contributions fixed as \% of OSR

Total Contributions vs. Benefit Payments Assuming asset shock and contributions fixed as \% of OSR

Employer Contributions vs. Pension Debt
Assuming asset shock and plans' statutory contribution policy

## Connecticut Retirement System 30 Year Projections

Plans included: State Employees' Retirement System, Teachers' Retirement System
State contribution policy at assumed rate of return (7.43\%)

[^31]Assets vs. Cash Flow
Assuming 5\% returns and contributions fixed as \% of OSR

Unfunded Liability vs. Funding Levels

## Assuming 5\% returns and contributions fixed as \% of OSR

Total Contributions vs. Benefit Payments Assuming 5\% returns and contributions fixed as \% of OSR

Employer Contributions vs. Pension Debt
Assuming 5\% returns and plans' statutory contribution policy

Unfunded Liability (Market Value) ——Funded Ratio

## New Jersey Retirement System 30 Year Projections

Plans included: Public Employees Retirement System - State, Teachers Pension and Annuity Fund
State contribution policy at assumed rate of return (7.5\% / 7.3\% / 7.0\%)

[^39]Fixed 5\% Economic Scenario
State Employees' Retirement System and Public School Employees' Retirement System

Assets vs. Cash Flow
Assuming 5\% returns and contributions fixed as \% of OSR

Unfunded Liability vs. Funding Levels
Assuming 5\% returns and contributions fixed as \% of OSR

- Unfunded Liability (Market Value)
-Funded Ratio

Total Contributions vs. Benefit Payments Assuming 5\% returns and contributions fixed as \% of OSR

Employer Contributions vs. Pension Debt
Assuming 5\% returns and plans' statutory contribution policy

| Model Assumptions |  |  |
| :---: | :---: | :---: |
| State | South Carolina Retirement System 7/1/2017 |  |
| Plan |  |  |
| Actuarial Valuation Used |  |  |
| Employer Contribution Policy |  |  |
|  | Scheduled ramp up in employer contribution rate to $18.56 \%$ in 2023. Contribution rate floor set at the rate needed to amortize UAAL within a set timeframe: |  |
|  |  |  |
| Description | 30 years in 2017 and counting down to 20 year amortization in 2027. Stays at 20 year amortization in subsequent years. |  |
|  | Employer contribution rate cannot be lowered until 85\% funded. <br> Employee contribution set at 9\%, can be lowered if employer contribution rate goes down. |  |
|  |  |  |
| If actuarial contribution policy |  |  |
| Applies to Amortization Period Amortization Method Type Open or closed | Prior to July 1, 2027 | After June 30, 2027 |
|  | 30 | 20 |
|  |  |  |
|  | Closed | Open |
| Layered or Single Amortization Amortization Payment Growth Rate | Single | Single |
|  | 3.00\% | 3.00\% |
| Additional Contribution Rules | Yes | Yes |
| If statutory rate |  |  |
| Applies to | Prior to July 1, 2027 | After June 30, 2027 |
| Rate | Employer contribution increases 1\% per year until reaches $18.56 \%$ in 2023. Employer contributions will stay at $18.56 \%$ unless that falls below the minimum actuarial rate. | After July 1, 2027 the board may raise the employer contribution rate by half a percentage point annually or, if the plan is at least 85 percent funded, lower it. |
| Employee Contribution Rate |  |  |
| Applies to | All |  |
| Rate | Employees pay 9\% |  |
| Employee Contribution Cost-Sharing | Yes, if funding levels improve sufficiently employee contributions will lower though will be at least half of the normal cost. Employee contribution rates can subsequently rise again if funding levels decline, with a cap of $9 \%$. |  |
| Actuarial Assumptions |  |  |
| Plan Assumed Rate of Return | 7.25\% |  |
| Inflation Assumption | 2.25\% |  |
| Payroll Growth Assumption | 3.00\% |  |
| COLA |  |  |
| Applies to | All |  |
| Description | Minimum of $1 \%$ or $\$ 500 /$ year ( $\$ 500$ not indexed). Wait period of 1 year. For early retirements, must wait until 2nd year following attainment of age 60 or 28 years of service if not retired |  |
| Assumed Effective COLA | Minimum of $1 \%$ or $\$ 500 /$ year ( $\$ 500$ not indexed). Flat 1\% COLA modeled |  |
| COLA Adjustment for Plan Funding and Investment Experience | No |  |

[^0]:    ${ }^{1}$ The United States Federal Reserve (2018) "Financial Accounts of the United States;" data and graphics illustrating the historical growth and status of the pension funding gap and growing vulnerability state pension plans have experienced since the Great Recession can be found appended to the conclusion of this analysis.
    2 The Pew Charitable Trusts. (2018). The State Pension Funding Gap: 2016. http://www.pewtrusts.org/en/research-and-analysis/issue-briefs/2018/04/the-state-pension-funding-gap-2016 for reported contributions by states; own source revenue information from the U.S. Census Bureau's Annual Survey of State Government Finances or the Annual Survey of State \& Local Government Finance.

[^1]:    ${ }^{3}$ The analysis examines 18 pension plans across the 10 states and is limited to state worker and teacher plans in every case. For Connecticut, Ohio, Pennsylvania, and Wisconsin, the plans we cover represent virtually all of what is managed and reported at the state level. A full list of the plans is noted in the methodology section and appended to this analysis.

[^2]:    ${ }^{4}$ California and Washington state have established reporting practices. Colorado published a comprehensive stress testing report in 2015, 2016 and legislation waiting for gubernatorial signature would continue that practice on an annual basis. Virginia, Hawaii, New Jersey, and Connecticut recently adopted legislation or policies requiring regular stress test reporting, while policymakers in Minnesota and Pennsylvania have proposed legislation or policies as of 2018.

[^5]:    ${ }^{14}$ Sources used in developing the capital market assumptions include the Federal Reserve, the Bureau of Economic Analysis, the Congressional Budget Office, and a variety of private sector and academic market researchers. See "Capital Market Assumptions 2017 Methodology" in Appendix I for further detail.
    ${ }^{15}$ A more detailed overview of the methodology behind our capital market assumptions and deterministic scenarios can be found in Appendix $I$.

[^6]:    16 This analysis is not intended to be a critique of actuarial assumptions. Differences between inflation assumptions used for actuarial purposes and those for investment forecasting are not uncommon - even within one state's own retirement system. This analysis does, however, provide additional information to suggest that the lower expected rate of return is reasonable.

[^7]:    17 State general own source revenue includes all state revenue sources, except for intergovernmental revenues, state-owned liquor stores receipts, utility revenues, and social insurance trust revenues. [^12]:    ${ }^{31}$ We consulted the Board of Governors of the Federal Reserve Systems. (2017). Supervisory Scenarios for Annual Stress Tests Required Under the Dodd-Frank Act Stress Testing Rules and the Capital Plan Rule. Accessed on June 29 , 2017 https://www.federalreserve.gov/newsevents/pressreleases/files/bcreg20170203a5.pdf For interest rate projections, we drew from the Congressional Budget Office. (2017). The Budget and Economic Outlook 2017 to 2027. Accessed on June 12, 2017 at https://www.cbo.gov/publication/52370. We relied on the U.S. Bureau of Labor Statistics for data on historical inflation, accessed at https://data.bls.gov/timeseries/CUUR0000SAOL1E?output view=pct 12mths.

[^13]:    ${ }^{32}$ In 2017 the state adopted an initiative to increase contributions over the next five years, with the goal to ramp up to making 100 percent of actuarial required contributions (ARC) by 2023; In July of 2017, to help ease this planned increase in state contributions towards the pension funds, New Jersey adopted legislation to transfer revenues from state lottery sales to the three largest state pension funds; finally, in January of 2018 the Governor and Legislature in New Jersey adopted P.L. 2017, Chapter 277 Assembly Bill No. 4704 requiring comprehensive annual stress testing of the five largest pension funds in the state. The legislation requires the results from the yearly analysis to be publicly reported, along with information on investment performance and disclosures of fees paid to outside investment managers.
    ${ }^{33}$ Calculations of pension debt do not account for the future expected value of lottery revenues.

[^14]:    ${ }^{34}$ Our projections include a one-time funding increase of nearly $\$ 1$ billion in fiscal years 2017 and 2018 for KTRS; but do not include the better-funded County Employee Retirement System (CERS). The reforms in 2013 also made changes to both KERS and CERS, which included a commitment to actuarial funding, a restriction on unfunded COLAs, and a cash balance plan design for future hires that shares risk between employers and employee.
    ${ }^{35}$ KTRS had total liabilities of $\$ 33$ billion in 2017 at the start of the projection period, while KERS liabilities were $\$ 17$ billion for the hazardous and nonhazardous plans combined.
    ${ }^{36}$ The state's attorney general filed a suit challenging the reforms shortly after they were signed into law, claiming they breach an inviolable contract, as well as alleging procedural problems with how the pension reforms were passed. The complaint is available at https://ag.ky.gov/pdf news/20160411 complaint.pdf.

[^15]:    ${ }^{37}$ See Act 9 in 2001 and Act 38 in 2002 of the Pennsylvania General Assembly contained significant retirement benefit enhancements for workers in the Public School Employees Retirement System (PSERS) and the State Employees Retirement System (SERS) plans.
    ${ }^{38}$ Act 120 in 2010 reduced benefit levels for SERS and PSERS new workers starting on or after July 1, 2011; and shared risk by requiring additional contributions if investment returns targets are not met. Act 5 in 2017 introduced two new hybrid retirement plans for all new SERS and PSERS workers hired on and after January 1, 2019.
    ${ }^{39}$ Estimate based on Pew's analysis of employer costs for the state and teacher plans as reported in the actuarial valuations from 2012 to 2016.

[^16]:    ${ }^{40}$ Aubry, J., \& Munnell, A. (2015). Final Report on Connecticut's State Employees Retirement System and Teachers' Retirement System. Center for Retirement Research at Boston College.
    ${ }^{41}$ Projections Report of the Actuary on the 2017 SEBAC Agreement posted by the Office of the Governor of Connecticut, available here: http://portal.ct.gov/-/media/Office-of-the-Governor/Press-Room/20170606-SEBAC-2017-Projections-Report-of-the-Actuary.pdf?la=en.
    ${ }^{42}$ This finding reflects the combined result for the Connecticut's State Employees Retirement System (SERS) and Teachers Retirement System (TRS) which now follow significantly different funding policies.

[^17]:    ${ }^{43}$ Because the fixed rate funding policies for both Colorado and Ohio are tied to payroll (which is projected to grow slower than revenue) the results based on the budget sustainable scenarios reflect a more optimistic outlook for employer contributions and slightly better results than under the state policy scenario, based on existing fixed rate funding policies. See Appendix I for a full description of the contribution scenarios and Appendix I.

[^18]:    ${ }^{44}$ The total employer contribution rate of 19.13 percent includes 9.13 percent in the base employer contribution rate for pensions, plus a total of 10.00 percent for the Amortization Equalization Disbursement (AED) and the Supplemental Amortization Equalization Disbursement (SAED).
    ${ }^{45}$ The reforms increased the age of retirement for some employees, required higher contributions from workers and employers, and reduced post-retirement cost-of-living adjustments (COLAs) for retirees. The 2010 reforms saved the state an estimated $\$ 15$ billion over the five years after passage. See Colorado PERA's Senate Bill 10-001 Report from December 2015 for details on the 2010 legislative reforms and impacts.
    ${ }^{46}$ Eason, B. "Lower PERA benefits, higher taxpayer and worker contributions proposed to close Colorado pension system's \$32 billion gap" The Denver Post, Sept. 22, 2017, http://www.denverpost.com/2017/09/22/colorado-pension-system-32-billion-gap/ ${ }^{47}$ See the 2015 Actuarial Valuation and pages 40-41 from the August 22, 2016 Cavanaugh Macdonald presentation to the Colorado Legislative Audit Committee on the valuation results; Technical insolvency is defined as less than 20 percent funded.
    ${ }^{48}$ Estimates based on projections provided by plan officials to Pew from the 2016 actuarial valuation for PERA which forecasts insolvency for Colorado PERA state and school divisions by 2041 assuming a 5.75 percent return or less. Similarly, our projections using fixed 5 percent rate of return with the state contribution policy assumption applied results in asset depletion by 2042. It should be noted that at the time of this writing, Colorado had not published audited 2017 investment return figures, but the state's returns have tracked closely with the Wilshire TUCS median return over the last several years. As such, we used this value as a proxy for 2017.

[^19]:    ${ }^{49}$ Continued monitoring to ensure that reform requirements are being followed is especially important in Colorado because of a constitutional amendment known as the Taxpayers' Bill of Rights (TABOR). TABOR severely limits the state's budget capacity and makes it much more difficult for Colorado, in comparison with nearly any other state, to raise pension contributions without a direct and corresponding cut to other lines in the state budget.

[^20]:    ${ }^{50}$ In 2012, Ohio modified current state worker and teacher benefits by lowering the multiplier awarded at later years of service, reducing COLAs, and tightening retirement eligibility (for state workers the retirement age was raised from age 65 with 5 years of service to age 67 with 10 years of service (YOS) and for teachers it was modified to ultimately reach age 60 with 30 YOS and age 65 with 5 YOS. In addition, the reform gradually increased contribution rates for teachers from 10 to 14 percent of pay.
    ${ }^{51}$ Based on Pew's database of state and local public retirement systems.

[^21]:    ${ }^{52}$ The projections for Virginia include the state portions of the state and teachers plans and do not include the political subdivision plans. Cities and towns are required by state law to make full actuarial payments, even in years in which the state is underfunding the main state pension plans, and, in the case of Virginia, including local employers had relatively immaterial impacts on the results or projections presented in this analysis.

[^22]:    ${ }^{53}$ The 2017 reforms package included provisions to lower the assumed rate of return for the pension plans from 7.5 to 7.25 percent, increases to employee contributions capped at 9 percent, and a schedule to increase employer contributions by two percentage points to 13.56 percent, then one percentage point each year after until reaching 18.56 percent in 2022. Our analysis includes required employer contributions toward the defined benefit for each worker, regardless of whether the employee elects to participate in the voluntary defined contribution plan or not.

[^23]:    ${ }^{54}$ The Pew Charitable Trusts (2018). The State Pension Funding Gap: 2016.
    ${ }^{55}$ As described in the 2016 actuarial valuation for NC TSERS, the Employer Contribution Rate Stabilization Policy requires increases in the contribution rate of 0.35 percentage points each year, with the rate never going below the actuarially determined contribution rate and never going higher than the actuarially determined rate calculated using discount rate equal to the longterm Treasury bond yield.

[^24]:    ${ }^{56}$ Wisconsin calculates pension contributions using a funding method that amortizes unfunded liabilities over the future payroll of active employees, which effectively results in paying off pension debt faster than the 25-to 30-year amortization periods typically used among public pension plans.
